

**Google Vaccination Sites**

Google plans to turn some of its offices in the US into COVID-19 vaccination sites, in collision with One Medical. <http://dgit.in/feb21-53>

**Walkable Chair**

Japanese startup's archelisFX straps onto the legs and disperses body weight, providing significant comfort. <http://dgit.in/feb21-54>

as an alarm so the intruder could be detected easily.” We wanted to know, step by step, how the intruder detection works, “In an office environment, the number of people is counted through radar or thermal grid array and matched by authorized mobile handsets. If there is a difference in the count then the intrusion is detected. Any unidentified MACID is recorded and an intrusion alert is raised. Further, on a proprietary application on mobile handsets, the location of the authorized person is shown and it helps the front office or colleagues to estimate his availability without disturbing them on phone (which is quite common in offices.).”

as a way to generate warnings/alerts.” They have their own in house proprietary software that has a few tricks up its sleeves, “proprietary software maps the data coming from multiple sensor locations and analyzes it to raise an alert based on timing, based on authorized/unauthorized person movements, change of security level, maybe identity confirmation through mobile biometrics or facial recognition, etc. In the future, these systems could form a platform for smart and secured home/office. Integrated with proprietary software, surveillance built-into the lighting unit will guide a visitor through the authorized route to a designated location.”

the Sun, a bit like sunflowers. Renkuba has come up with an innovative solution where the tracking is digital. It is all in the glass itself, and is a totally novel technology, “Renkuba has designed an innovative glass for solar panels that is capable of optically tracking the sunlight. The unique patent pending design of the glass can capture more sunlight in the morning and evening when the panels do not generate peak power and thereby we improve the efficiency of the solar panels.

The panel with Renkuba glass once it is deployed has no moving parts and hence no maintenance overhead. As we use stationary optical element i.e glass to track sunlight we call this Motion Free Optical Tracking solution. Renkuba panels are installed just like regular solar panels and similarly, there is no additional maintenance for Renkuba panel other than regular solar panel cleaning. Today's solar panels have a flat glass. We replace this with our Renkuba glass which has inbuilt “Light Deflector Units” to redirect more sunlight to the solar cells underneath. The Light deflector units have patented grooves which are designed by complex topology optimisation algorithm; total internal reflection and our unique glass design can capture more sunlight irrespective of the movement of the sun in the sky for all 365 days and for all geographies.” We wanted to know what this means in a price sensitive market, “Renkuba panels have a 10% increase in capital cost that is inclusive of the price of the special glass and the project cost. But an end consumer using our panels will get their ROI in 3 years as opposed to the existing 4 years period for solar. A residential user using Renkuba panels also continues to earn 20% more revenue year on year (as compared to traditional solar panels).”

BelBird surveillance hardware

It is different at home, “in the home environment, motion sensors and MACID scanners are mapped in each room. If the system detects the presence of people without authorized MAC IDs then an alert is generated. This feature will help in monitoring people who have been home quarantined, which is currently a serious problem. Deployment is similar. But the app running on a server and mobile handsets will be quite different because the surveillance needs are different. For example in the home when the owner is at home he does not need surveillance inside the home. Whereas in the office detection of an unauthorized person is crucial even if authorized persons are present inside. Audio signals can be used

The home surveillance system is particularly useful for tracking and monitoring the elderly and children, without distressing them, “in the home environment, one can keep a watch on the elders without creating discomfort for them. Further by analyzing their movement patterns, like going to the restroom, and time spent in bed, living room, and restrooms. Emotional stress and physical ailments affect their daily routines, which could be easily captured through our surveillance system without affecting their privacy.”
