

Razer Project Brooklyn

Razer recently revealed a gaming chair concept, dubbed Project Brooklyn.

What makes Brooklyn special is the fact that it's very versatile, capable of taking different forms as per the user's needs. However, the most impressive thing about the chair is the massive foldable display that fits inside the backrest of the chair when it's not in use. The 180-degree, transparent OLED screen slides up

from the back of the chair and then folds down in front to surround the person currently seated in the chair. Fully extended, the screen measures 60-inches, and gives a wider FOV than most three-screen setups might give you. There's also a table that, like the screen, is foldable and can be popped out when needed. It extends from both armrests to meet in the middle and form a single platform. Razer calls these "transformable 4D armrests". That's not all, Project Brooklyn's chair is also fitted with Razer HyperSense modules, so you have haptic feedback on this chair. It also comes with Razer Chroma RGB, which you can probably sync with your other Razer products. For the time being, however, Razer Project Brooklyn is just a concept.

Raspberry Pi Pico

When it comes to mini computers, few are as well known as the Raspberry Pi. Usually, a Raspberry Pi is the whole package, with an HDMI port, USB ports, and it runs open-source OS and basically it can do all the basic functions one might expect of a computer. However, the new Raspberry Pi Pico is built for more complex functions. On its own, it doesn't do much, but pop a few add-ons, and you've got a complex machine that can perform complex tasks, from controlling robots, to lights, and more. And of course, in line with most Raspberry products, it's dirt cheap at just \$4.

Microcontrollers aren't exactly a new thing, but this is a first for Raspberry Pi. Another first for

Pi is that, with the Pico, this is its first attempt at making its own chips. The Pico comes with Raspberry Pi's new RP2040 chip, which consists of an Arm Cortex-M0+ processor with 264KB internal RAM. It also supports Flash memory storage of up to 16MB. The chip runs on a 40nm process and has dual cores; which is a steal for a board that only costs \$4. Raspberry Pi COO, James Adams said that the company started working on the chip back in 2016.

Fujifilm 580TB magnetic tape

Fujifilm has reportedly set a new world record by creating a magnetic storage tape that can store 580 terabytes of data. Yes, 580 TB. Developed in partnership with IBM Research, the tape uses a new magnetic particle called Strontium Ferrite (SrFe), which is commonly used to make motor magnets. Fujifilm was looking into using Strontium Ferrite as a successor to Barium Ferrite (BaFe) which is the go to material for storage right now. SrFe seemingly has plenty of benefits over BaFe, starting with higher magnetic characteristics and 60 percent less particle volume. SrFe is also a chemically stable oxide, so it's good for the long term as well.

The tape can store a whopping 317 gigabytes per square inch. IBM have also worked on a new low friction tape head, which is reportedly very fast and accurate. As mentioned by IBM Research Manager Mark Lantz, "When

tape is being read it is streamed over the head at a speed of about 15 km/h and with our new servo technologies we are still able to position the tape head with an accuracy that is about 1.5 times the width of a DNA molecule." Everything put together, these storage tapes are 50x better than the best tape storage we have in the market today.
