

all the encoded text strings while enc_inp is a log of all the text strings before encoding. Similarly, the Decrypto! function logs are stored in the dec_out and dec_inp files.

JHIDE

JHide is a basic steganography tool that allows you to hide messages, text files or actually any kind of file inside an image. This image can then be shared with others, or hosted on the internet for people to download, without anyone knowing that there is a secret payload attached to the file. Note that social media platforms, internet forums, or instant messaging apps that process or modify the file can lead to loss of the hidden message or file. So if sharing an image file with a payload on apps such as Telegram or WhatsApp,

which is totally optional and provides an additional layer of security. Now to unhide the file, the process is relatively simple, just select the image that has the secret additional file, and the destination. The software does not prompt you for a password at this point, even if one has been used to hide the file. The output of a decryption process is a .zip file at the selected destination. To unzip this file, the password needs to be keyed in, into whatever unzipping software is used.

The best thing about this tool is that it works just as well on animated gifs, which means you can appear to be spamming Discord while actually carrying out a secret conversation.

Hiding a text file inside a .png file

make sure to share the file instead of sharing it as an image upload. Also note that the software only works with the .png, .gif and .tiff formats, and not the .jpeg format.

To hide a file inside an image, you have to choose a carrier image, the file to be hidden and a destination. After that you can decide to add a password,

isolated container within which all the encrypted files are located. Only you will have access to the vault, which is protected by a password. The contents cannot be accessed without the password, so the software generates a recovery key on the generation of a new vault, which is a string of random words that can either be printed or

Creating a vault in cryptomator

saved as a text file. Note that the application offers no other method of recovering your password, and if you do not create the recovery key and forget your password, you can only hope for advanced quantum computers to decrypt the data. It is a pretty simple setup, after which you can lock or unlock the folder using Cryptomator. If the folder is unlocked, all the files are accessible and you can use them normally. If the folder is locked, the files are hidden away and encrypted, and cannot be opened or used in any other software. Now note that all the contents of the folder, as well as the directory structure is changed as a series of operations that take place every time the vault is locked or unlocked. To make this easy to handle, Cryptomator allows you to mount the vault as a virtual drive, that can be mounted when revealed, and unmounted when hidden. If this approach is used by the user, the vault becomes a drive that magically appears when you need to hide stuff. Users can also create multiple vaults, and mount all of them. Integration with OneDrive is so seamless, that it is just like working with the files locally. 

CRYPTOMATOR

Cryptomator is an ideal solution if you want to encrypt a large number of files, protect them with a password, and store them securely locally, or in the cloud. The software is deeply integrated with Microsoft OneDrive from the get go, and supports other cloud storage services such as Google Drive and DropBox too. To use the software, you have to first create a vault, which is a secured,
