

## How your brain interprets colour

New studies show how the human brain interprets and perceives colour. <http://digit.in/mar21-15>

## An ultrathin endoscope

An Endoscop the size of a human hair is now being used to image neurons firing in the brains of living mice. <http://digit.in/mar21-16>

Credit: Encorbio

↑ This is an image of glial cells in a rat's brain. The flattened fibroblastic cells appear mostly in green. The blue spots are nuclear DNA.

Credit: Encorbio

↑ Another image of rat neurons stained with chicken antibodies causing the red highlights in the cell features, while the blue DNA is stained with a dye.

Credit: V Wedeen, MGH, Boston

← The highlighted structure in this image is the corona radiata, a sheet of white matter that carries all the traffic through and from the cerebral cortex.

Credit: CBS/Harvard

← The technique of staining individual cells in neural tissue using a palette of fluorescent proteins, is appropriately enough called the "rainbow".

Credit: David S, Paul M

← This is a slice of the brain showing diffusion tensor imaging data, with each pixel being a glyph that indicates the direction of water diffusion.

Credit: David VE, WU-Minn HCP Consortium

← The colours in this map represent levels of functional connectivity between brain regions, and was made by combining multiple imaging techniques.

Credit: CBS/Harvard

← Harvard researchers created a technique that dyes axons and dendrites in different colours allowing them to track individual brain cells.

Credit: Vishal Patel

← A visualised slice of a diffusion tensor imaging dataset, the red green and blue colours indicate motion of water in the brain along the three axes.
