

Mi Air Charge

Wireless charging, at least the kind we're currently used to, is not exactly commonplace. We're talking about the inductive charging pads where you can place your device on them to start charging. We usually see high-end and premium devices adopting this form of charging.

According to XDA, Xiaomi is already set to go even further beyond, with what could only be called "true", touchless, wireless charging. We're talking being able to charge devices

from meters away, and that's what Xiaomi claims Mi Air Charge Technology will be able to do.

As of right now, Mi Air Charge Technology is a 5W charging system that uses 144 antennas to send millimeter wide waves to your device, i.e., your phone. This is similar to mmWave 5G that currently has a very short radius.

The device receives them on a 14-antenna array of its own. According to Xiaomi, this is just the beginning, eventually, Mi Air Charge will be able to charge multiple devices at once, be able to pass through physical objects and be able to charge other smaller devices around the room as well, from smartwatches to speakers.

eXciteOSA

This is a gadget for better sleep, because we all could definitely use some. The eXciteOSA is a device that supposedly helps relieve people who are suffering from snoring. Snoring is something that is not only a hassle for the person snoring, but also for anyone else who happens to be sleeping in the vicinity. The eXciteOSA, which is reportedly approved by the U.S FDA (Food and Drug Administration), is a device that can not only help alleviate snoring, but you also don't even need to wear it at night while sleeping.

This is certainly a very unique device, in that it works by stimulating your tongue. What this does is clear the person's airway, which is what tends to get blocked while sleeping. This blockage is what in turn causes snoring. eXciteOSA stimulates the users tongue muscles because research indicates that it's not the nose or the nostrils that are to blame for snoring, but the tongue. eXciteOSA uses four electrodes, two placed above the tongue and two below, to deliver stimulation in the form of periodical electrical pulses. Nothing too strong to worry about. All users need is to use the device for 20 minutes a day, over a course of six weeks. Post that, it needs to be used only once a week.

Brain E-Tattoo

Brain Scientific, Inc's Brain E-Tattoo is not your conventional body tattoo. It doesn't resemble any tattoo you've ever seen before. It simply looks like a small patch, about the size of a stamp. If anything, it almost looks like you've stuck a microchip on your head. Which is actually true. If you happen to get yourself a Brain E-Tattoo, what you've done is give yourself a minimally invasive, implantable, 4-channel, micro electroencephalography (EEG) with graphene electrodes. Its purpose? To monitor your brain

24x7. No, not in a sinister way, it's for health purposes. This is the future of brain monitoring and it's as minimally invasive as it gets. Once printed, the E-Tattoo can monitor brain activity and transmit the data wirelessly to the cloud. Over there, using Brain Scientific's A.I tools, the data can be analysed for any changes, including signs of epileptic seizures or even neurodegenerative diseases like Alzheimers.
