

Myllo

This powerful software lets you take control of your photo storage and backup needs

There is a whole philosophical, ethical movement behind what Myllo is, which is just an example of what is known as the Gaia framework. You can read all about it over at <http://digit.in/myllo>, but without going into too much depth, the fundamental idea is that humans will be able to take control of and maintain privacy of their digital belongings and that our phones or computers are not merely terminals to access cloud services, and that there will be a shift towards distributed computing again. The product of all this considered thought is Myllo, a totally unique and easy to use software that lets you organise your photos in three simple ways. First, all your photos from all your devices are easily accessible at your fingertips or mouse pointer, on

any device. Second, you can back up and sync between devices, and automate the backup process as well, on a local device or external storage. Third, it is a platform agnostic and versatile software that will fit right into your existing setup.

If you store all your images on cloud storage, you can use Myllo to set up a secure encrypted vault and use the cloud storage offered by OneDrive or Google. If you have a smartphone from which you periodically copy images, you can automate it. If you are a photographer looking for a free alternative to

where that text was found. You can set up the software in such a way that old photos are automatically deleted from your mobile phone, and backed up on an external hard drive or NAS storage. For a photographer who travels a lot, Myllo lets you quickly sync up photos between cameras and laptop, by using the phone as a hotspot to create a private network for syncing between devices when there is no internet connection.

SETUP

It is recommended that the software be installed on a PC or laptop first. Once installed, there is a tutorial that walks you through the entire configuration process, along with prompts to make sure that everything is setup properly. In the dashboard, you can add all the devices between which Myllo syncs the data. The computer that you install Myllo on is obviously added by default. After that, external hard drives, phones, cloud storage and other devices can

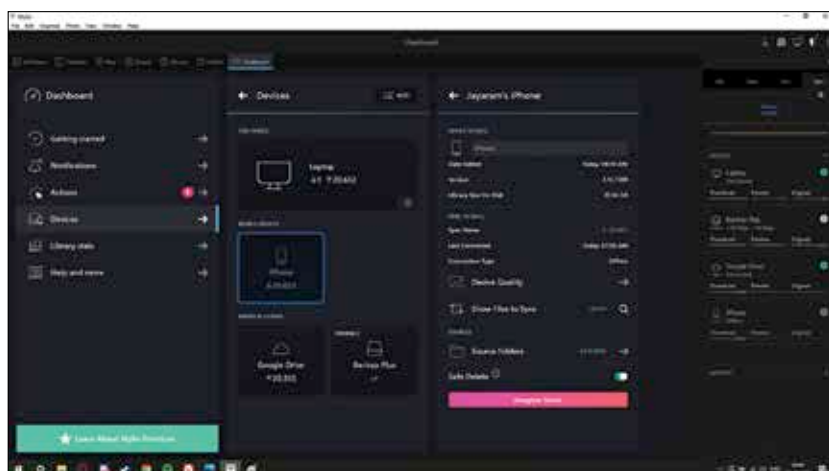

Lightroom, Myllo has all the necessary features. This is your own personal Google Photos, that connects to Google Photos. Your phone, your cloud storage services, your social media accounts, your personal computing devices, your external hard drives, and NAS.

Myllo has a lot of advanced features hidden away. All photos are scanned for OCR and searches show images

be added. Now, the main thing is that every device has a toggle for quality, which are thumbnail, optimised and original. Users have to just pick the appropriate quality for each of the devices added, and the software does the rest, uploading or downloading the images at the set quality on the device. Any device that has "original quality" is where all the images are "vaulted". That is all the highest quality images from all the added devices are stored in these vaults. If a user has two vaults set up, that means they have two copies of all their images, which is the recommended number by the software itself.

Now, Myllo can be installed on the smartphone. Through the smartphone, there are some additional services that can be added, which are not available on the desktop version. These are Flickr and Facebook. All your photos, and the ones where you have confirmed you have been tagged are downloaded into the app and synced across devices. The easiest way to set things up is to use thumbnails on all device settings,
