Complications

Complications are additional features on a watch that go beyond indicating the hour, minute or second.

Moon phase

The Moon phase complication not just looks really good, but is functional as well. About half of a disc is visible through a carefully designed aperture on the face. This disc has two complete Moons that take turns moving across the complication as the disc turns, though only one is visible at any given point of time. The aperture has two circular projections, that simulate the shadow cast by the Earth on the Moon. Through the aperture, the watch thus shows the Moon as it would appear in the night sky, using a portion of the watch face itself as the shadow.

Chronograph

A chronograph is essentially an analog stopwatch, and all the features that you can expect to find in a stopwatch app also has a mechanical equivalent, such as double chronographs for lap timings, or flyback chronographs to reset the needle while it continues to tick. There are highly specialized chronographs with jumping seconds, known by the fancy term *foudroyante*, where a smaller dial has a needle that goes around once every second, allowing for split second timing.

Calendars

These watches have grown out of the previous types of watches. Typically, a watch with a calendar function requires the user to keep track of months and leap years, but the more advanced models have mechanisms in place that allow users to go for a whole year before making adjustments, known as Annual Calendars, which only need to be reset at the end of February every year (the outlier case when it comes to days in a month). Perpetual calendars can also keep track of Februaries and leap years, thus requiring minimal adjustments.

LeCoultre

Tourbillon

A tourbillon is a mechanism that counteracts the effect of gravity on the watch, as well as the watch turning in any which direction. They may be hidden and work just the same, but the parts are so delicate that watchmakers like to show them off, often exposing just the tourbillon, while the rest of the mechanism is under the face. Shown above is the Greubel Forsey DT30°, a tourbillon inclined at 30 degrees located within another tourbillon, making it a double tourbillon.
