

content and we won't argue with you there, well, not today at least. But the future looks bright for streaming services. Today, users can stream content in 4K, HDR, Dolby Vision and Dolby Atmos without breaking a sweat, provided you have a fast enough internet connection. Streaming services like Netflix, Amazon Prime Video and Apple TV are hard at work improving the quality of their streams and within the next decade or so, we will have blu-ray quality content on our TVs without resorting to relying on the physical medium.

2. A truly wireless setup

Today if you own a Sony BRAVIA TV and a Sony Soundbar chances are you can connect the two wirelessly for a clean and immersive setup. The same is the case for Samsung TVs and soundbars and LG as well. But what if we told you that you could connect an entire home theatre to your TV without a single wire running between the TV and any of the 5.1 or 7.1 speaker setup you have? No amplifier either! Yes, it is becoming a reality today and will be a norm in the coming decade. Klipsch currently offers its reference wireless 5.1 sound system. If you have an LG OLED TV from 2019 or newer, then these speakers will connect wirelessly to the TV. One of the biggest challenges of building a home theatre today is the clutter of wires connected to the amplifier. Here, with truly wireless connectivity, you are getting the convenience of a soundbar with the performance of a dedicated home theatre. In the future, a lot more brands will start offering this technology and in a decade or so, we will see this technology changing home theatre setups for good!

3. A longer shelf life?

The transition and improvement in the quality of TVs were quite drastic over the past decade. While TVs typically have a 5-7 year life, it looks like we could get more life out of our TVs for two reasons - advancement in technology and the stagnation of some peak TV technology. Let me explain. The difference between the

A truly wireless setup

LG C9 from 2019 and C1 from 2021 isn't enough to warrant an upgrade. If you have the Sony X950G from 2019, you have a TV that is far superior to most premium TVs today in terms of panel performance. If three years of technological advancement isn't enough to wow tech enthusiasts like us, then how will that affect you? If you invest in a high-end TV today, chances are you are set for the next decade and that's when we think TV technology will get super interesting.

4. Rise of newer backlighting technologies

From CRT TVs to LED and now OLED TVs, we've seen different forms of backlighting power TVs. 2020 and 2021 have seen the rise of Mini LED TVs. TCL and Samsung both have their Mini LED TVs

on offer and Mini LEDs bring the advantage of LED TV like brightness and OLED TV like contrast and black levels giving users the best of both worlds. The horizon looks bright (no pun intended) for TV backlighting technology. And that's not it, we have technologies like MicroLED, Quantum dot OLED (QD-OLED) and Quantum Nano Emitting Diodes (QNED) to watch out for in the TV space in the coming decade. How they affect the representation of the content is only something time will tell.

5. Moore's law is coming into effect

The only place which may not be as significant a jump in the next 20 years is resolution. While the jump from SD to HD was fast and the jump to 4K even faster, we are still strug-
