

sive. At CES we've seen multiple concepts where if you sit at an angle, then the same display can give viewers two different experiences, full screen. That's like taking advantage of the entire display without fighting over the remote. Imagine a future where you spend time with your significant other without fighting over what you want to watch because you will both be watching exactly what you want.

12. A TV with a built-in PlayStation or Xbox, or both?

In 2010, Sony released the Bravia KDL-22PX300, a TV with a built-in Sony PlayStation 2. While the trend of TVs with built-in consoles never took off, we think that is changing with the evolution of game streaming. Speaking about streaming Xbox games to a smart TV via xCloud, in an interview with the Verge, Head of Xbox, Phil Spencer said, "I think you're going to see that in the next 12 months. I don't think anything is going to stop us from doing that. I thought what you said about the TV was spot on. What we used to call a TV was a CRT that's just throwing an image on the back of a piece of glass that I'm looking at. Now, as you said, a TV is really more of a game console stuffed behind a screen that has an app platform and a Bluetooth stack and a streaming capability. Is it really a TV anymore or is it just the form and function of the devices that we used to have around our TV, consolidated into the one big screen that I'm looking at?"

We agree with what Phil Spencer says. While there is still no news about xCloud making its way to smart TVs, the future isn't far. Today we can stream games from consoles and PC to a TV in a different room but that requires some form of additional hardware connected to the TV like an NVIDIA shield, for example. Imagine a day, when you launch the PlayStation app to play the next God of War video game on your smart TV instead of firing up the PlayStation? Wouldn't that be cool? We could certainly see the Netflix of gaming becoming commercially feasible in the next 20 years.

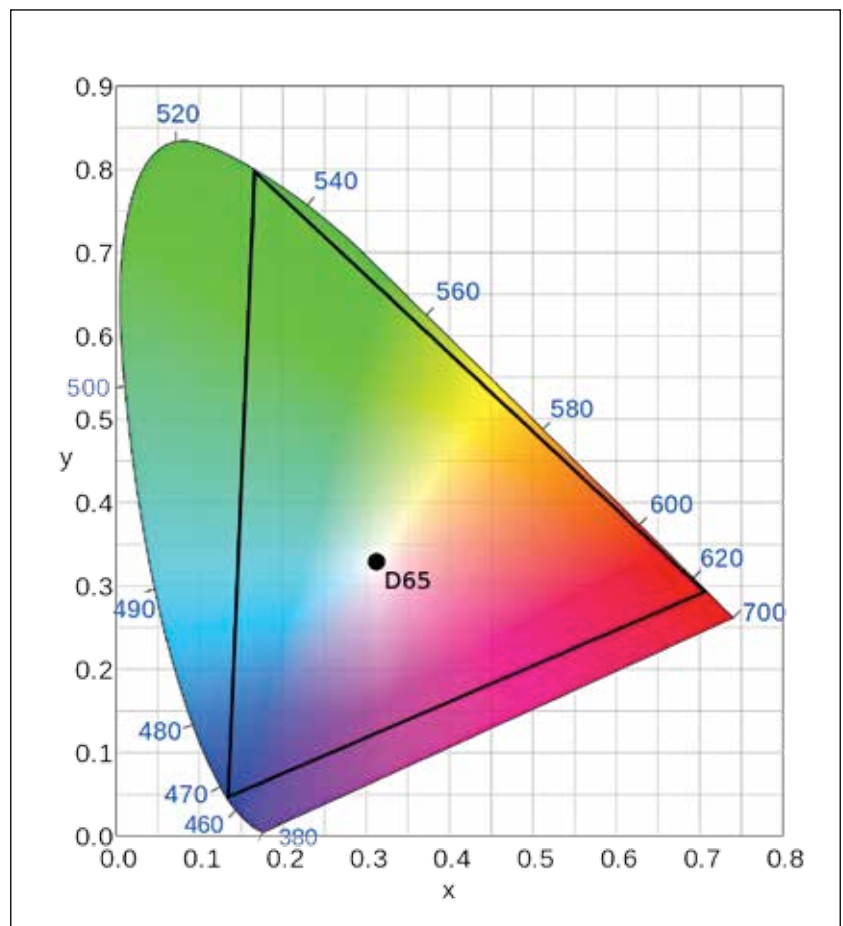

Foldable TV - Space saving and anxiety-inducing at the same time

13. Connectivity: Beyond 4G, 5G and Wi-Fi

5G and game streaming have been synonymous ever since 5G was announced and to fulfil the dream of lag-free game streaming at high resolution, we will need internet speeds much faster than what we have today and lightning-fast latencies. A smart TV today isn't so smart without an internet connection. And the limitation of your new smart TV has more

to do with your Wi-Fi router than the TV itself. What if we were to eliminate the weakest link? What if true wireless connectivity were present all the time across all devices, with each device acting as a range extender/booster when needed? Having the ultimate wireless internet connectivity can not only help solve the problem of streaming but also help bridge the quality gap found when streaming over Wi-Fi.
