

them to go to, we have the framework for the app. Now to add the content.

SETTING UP CONTAINERS

We will be adding a nicely formatted list of games for the user to see, once they have decided if they want to check out games for large or small parties, and for how many particular people. To do this, we will be going for a simple scrollable list, but you can choose to swipe left and right, or chain up more elaborate interactions that take users down to individual pages. Whatever floats your boat. We extended the length to something like 2000, and started adding the individual pieces of content. For the games for large parties, we are going to have the title of the game, a picture, a short description, and a button to buy the game on Amazon. Now once you have set up the title, rating, description, image and purchase button, it is a good idea to group all of these together into a folder and give it a name. This bit here is just like working with those complex images in Photoshop with many layers, so you have to be careful about organisation. The UI elements can be bunched into folders that can be named, and these folders can be copied and pasted as a group. This allows you to quickly make containers for scrolling all the games in all the screens. To add a container to a page, simply drag the container to the appropriate page. When you do this, you can select and choose the scrolling properties, that instantly convert your boring scrolling container into a carousel, by snapping to the pieces of content. If you spaced out the content properly in either the vertical or horizontal scrolling containers, it should work like a breeze. To use this option, check "Treat scroll container as snap (carousel)".

Setting up the containers

A container that acts as a home button

SMART CONTAINERS

Containers are incredibly useful as you can put in all kinds of smart interactive UI elements into a small container, chain up a bunch of different states, and create really rich interactive experiences. For example, while it is laborious, you can create a rating bar that actually allows users to give their own rating to each of the board games. The main principle to be demonstrated here is that containers can actually behave like mini pages on their own, embeddable bits that have a lot of functionality. For example, once we made the app we realised that we had

not put in any way for users to go back to the home screen. To do this, we added a card from Monopoly, as an image in a box in a container of the same size. When a user taps on this box, they are taken to the home screen. This container can be placed at the end of the pages as needed, but that would interfere with the scrolling as the container would always stay at the bottom of the page. The better idea is to embed it within the other container (yes, containers can be nested) directly, so that it shows up after users have scrolled through all the games! 📱
