Tech Smart vs Space Smart

Deepak Gupta, Country Head South East Asia at ZOTAC Technology Ltd.

The cohort of Generation Alpha (Early 2010s-Mid 2020s) will entirely be born in the 21st century and with two and a half million newborns being born every week as of 2015, the estimated size of this cohort will be two billion by 2025.

A 2019 survey was conducted by LEGO and The Harris Poll, to commemorate the 50th anniversary of the space launch of Apollo 11. The survey polled 3000 children aged 8 to 12 and found that one out of three children in the US and UK preferred to be a vlogger rather than being an astronaut. Of the kids polled, 75% thought humans will live in outer space or another planet soon, and 75% want to go to outer space or live on a different planet. The data points from this study are fascinating for us hardware manufacturers as it assures us that the demand for hardware will always be on the rise in the future.

To stand out as a content creator in a world where children start getting exposed to technology as early as 2 years old, and with attention spans being so low, unique and high-quality

content needs to be created daily. Many content creators these days choose to be gaming streamers as it is entertaining as well as accomplishes the goal of being a vlogger. Then, in an age of technological advancement: 4K Gaming, 4K Content, and VR Gaming are new incoming trends. All these would require heavy usage of Desktop PCs for streaming, rendering, and transitioning of content.

Computer Science techniques have helped astronomers explore the universe with the help of Deep Learning. Deep learning finds telltale arcs of light that indicate massive objects. To make complex groupings, astronomers have extensively used statistical machine learning techniques like neural networks, which are programmed systems with layered nodes connected in a web similar to neurons in the human brain. Deep learning just involves more interconnected layers or steps in the computation, including “hidden” ones of increasing complexity as the algorithm proceeds from input to output. The computational requirement in deep learning requires training a large dataset. Hence, a GPU is an optimum choice to compute data efficiently. The larger the computation the more ideal will be the application of a GPU.

Though polar opposites, career options of being a vlogger or an astronomer are both dependant on similar technology, and their professional needs do not get fulfilled with a smartphone. Even laptops have drawbacks in terms of the specifications they provide, as a high specced laptop is heavy and bulky.

Generation Alpha will require ease in transferability, but will also need the high-end specifications that pocket-sized desktops can offer. With wireless peripherals already the norm, pocket-sized desktops will be the next-gen technology offering the right mix of power and portability. After all, Gen Alpha is going to need to quickly set

up something that can stream in 4k from anywhere, or something which they can take to a library and do Deep Learning Experiments on.

The parallel processing design of a GPU has seen it being adapted in varied fields where AI is being used, such as medical research, military and defense systems, security and surveillance, manufacturing, autonomous flying, etc. Currently popular in gaming and video rendering; future GPU speed enhancements provide a slew of new possibilities for demanding applications like computational graphics, computer vision, and a variety of other high-performance computing tasks.

It's ironic as I write this article, I will be attending my first ever virtual Computex from home. What we used to visit, touch and feel are now available and visible in the comfort of our home. This makes me wonder if our world will soon become ever smaller and connected, yet so distant.

When the need arose to counter the outbreak of COVID-19, it was the gamers and NVIDIA who helped out medical researchers and data scientists to understand the novel coronavirus. NVIDIA encouraged people to download the Folding@Home application to accelerate the research. This application is a well-known distributed computing platform that uses public number crunching power to help look for a cure for cancer, or in this case, ways to counter the deadliest pandemic in a century. It's no surprise that PC hardware is what leads this effort.

Preparing for the future needs of Gen Alpha starts now, and ZOTAC has revolutionized portability with our latest ZBOX MAGNUS One Series giving you the power of latest GeForce RTX 30 Series GPUs, providing high-fidelity ray-traced graphics and cutting-edge AI features with DLSS specifications, all in a package that's the same size as a small UPS. So whether it's tech smart or space smart, in a future with varied computing applications, both the cohorts will have mini desktops from ZOTAC that fulfils their needs.
