that running mining software reduces the endurance of graphics cards, it shouldn't be far-fetched to realise that farming Chia should kill your SSD earlier than what they're rated for.

Back when the cryptocurrency craze first started eating up GPU stocks and lots of GPUs were returned by miners for warranty claims, manufacturers took cognisance and reduced the warranties on graphics cards that were used for mining cryptocurrencies. Crypto

mining on graphics cards leave tell-tale signs that manufacturers can easily identify. With SSDs, the wear is also easily identifiable. Normal SSD usage and farming Chia coins have significantly different wear patterns. So manufacturers will be able to deny warranty claims on SSDs used for Chia farming. In fact, GALAX has already stated that they will not be honouring warranties on SSDs suspected of having been used for Chia farming. Also, the obvious sign

would be that if your SSD crashed, then it would do so with the Chia plot on it. While you might not be able to delete the plots before giving it for a warranty claim, the SSD manufacturer will have no problems reading data off a dead SSD. PNY has already started slashing warranty periods on some of their new SSDs. And it won't be long before the other manufacturers follow suit. So get your SSDs before they become super expensive like how graphics cards are.

BUYING ADVICE

GAMING LAPTOP IN 60K

Q Hello Agent001, I am looking for a new gaming laptop as I am an engineering student and I have a lot to do with software. I'm also gonna use it for games in my spare time. I'm confused about the graphics, processor and all that stuff. Below are some of the basic specs which I have sorted out myself.

Specs:

- Price - Between 60-70k.
- Processor - Can be AMD or Intel
- Ram - Min 8 GB
- Graphics - More than 1050
- Storage - 1TB or 512 GB (Or both)
- Battery - Doesn't matter

I really need some suggestions for it and I know you are gonna help. Thanks in advance.

—Rashmi

A Hey Rashmi, Let's tackle each parameter one-by-one. In the price bracket you've specified, you're most likely to find either an AMD Ryzen 5 4600H or an Intel Core i5-9300H. Between the two, the AMD Ryzen 5 4600H is miles ahead of its Intel counterpart across all sorts of workloads. And this includes gaming as well.

Then we have the memory capacity. 8 GB is all that you're going to get in this price bracket. And it would be

best that you purchase another 8 GB module and have that installed. Laptops running with just a single RAM module gets a performance penalty compared to those running a dual-channel setup. You will need to find a compatible memory module. To do that, install a software such as CPU-Z that can list the OEM of your RAM module along with the timings. It's best to get a RAM module the same MT/s rate along with the appropriate timings.

Then comes the graphics card. You will get laptops with a GTX 1050 around the 53-55K price range and when you get to laptops that come within the 55-59K segment, you will find laptops with the GTX 1650, and even something better during sales.

So you should ideally look for one with the GTX 1650.

For storage, you need to get an SSD. Windows laptops without SSDs get excruciatingly slow over time and it's only made bearable when you have an SSD. Laptops will usually come with a 256GB or 512GB PCIe NVMe SSD coupled with a hard drive. That's the best combination because it gives you storage capacity and speed.

You can get several laptops meeting this criteria in your price range. The Acer Nitro 5 (NH.Q9MSI.001) and HP Pavilion Gaming (15-ec1024AX) have all the above mentioned specifications, except for the RAM. You will only get 8 GB and our advice to buy another module still stands. Happy gaming!

HP Pavilion 15-ec1024AX
