

Next@Acer global press conference

The company served up the usual mix of a few notable products sprinkled among a sea of rote upgrades. <http://dgit.in/jun21-31>

Asus ROG Gaming Laptops

Asus has launched new gaming laptops in India in its ROG Flow and ROG Zephyrus ranges. <http://dgit.in/jun21-32>

Learning Automation the fun way

Let the robots handle the mundane tasks

Xavier Das | feedback@dgit.in

In modern times, we have seen the emergence of the concept of Robotic Process Automation, commonly known as RPA in the IT world and also several tools by which it is achieved. Robotic Process Automation is the process of automating a manual task or a set of tasks involved in a business by the means of AI or by a script that has been programmed to take care of the same. One of the major benefits that RPA offers is to streamline operations and reduce costs.

In today's times we have several tools that help us with RPA and the majority among them are licensed tools like UiPath, Blue Prism and Pega OpenSpan. However, there are

also python libraries, which may not be as useful for industrial RPA as the aforementioned tools; they do go quite the mile in giving us a high degree of automation and Python being an open source community, is always under continuous development and there's no reason to not believe that the Python libraries too will become just as good, if not better.

Let's take a look at one of the python APIs for automation called pyautogui which lets our script control the mouse and keyboard allowing us to interact with other applications.

It's a very simple package in its own with simpler syntaxes that will become second nature to you once you start using it already. Let's go over a few fundamentals and then we can dive into a nice use-case done step by

step with the help of pyautogui and a few other libraries (pyautogui being the center of focus).

To begin with, we can do the basic input operations like getting the position of the mouse, clicking the mouse, moving the mouse, pressing keys from the keyboard, performing hotkey operations etc. In the example right here, we have two very simple commands called `pyautogui.size()` and `pyautogui.position()` which simply returns the size of the screen and the current position where the mouse is currently pointing to. Simple enough, right?

```
import pyautogui
screenWidth, screenHeight = pyautogui.size()
currentMouseX, currentMouseY = pyautogui.position()
# Get the XY position of the mouse.
print("the dimensions are ({0}, {1}) and the position of the mouse is at ({2}, {3})".format(
    screenWidth, screenHeight, currentMouseX, currentMouseY))
```

```
import pyautogui
import time
time.sleep(2)
pyautogui.write('Hello world!', interval=0.10)
pyautogui.keyDown('alt')
pyautogui.press('tab')
pyautogui.alert("Switching windows here")
```
