

bring even more revolutionary changes. Technologies such as artificial intelligence, Internet of Things are set to radically transform the way we live, work and play. There will be plenty of changes that none of us are able to foresee at the moment, but we can definitely predict the way we see the world unlocking. Some of the top inventions and technology that may define future of PC industry can be much advanced and ahead of the world we are living in today.

Privacy will be one prime area where we will see most of the brands and companies investing in the coming years, as people demand more privacy in the Internet age. Increased privacy will be especially important as digitization efforts continue impacting the way we store memories and documents from the controlled level all the way down to the personal. Inspired by this, we also expect an increased move towards cloud-based storage. Creation of digital IDs will provide more ownership to the users over their data. As hacks and data breaches continue to proliferate in the connected ecosystem we live in, privacy will become the core of future inventions and we will see gadgets, especially personal computers to come with enhanced security capabilities.

For the past decade, laptop makers have tried to make their products more tablet-like; the next decade could see manufacturers making laptops more like phones. Over the years, PCs will evolve to take various forms and shapes, becoming more lighter, thinner and portable in design. Like the secondary screen was a groundbreaking trend in past few years, one of the biggest trends coming to the PC market in coming decades is expected to be foldable displays. In next 20 years, we can expect to see computers in smaller, portable form factors, with displays which can be used as a standalone device or devices which can be multi-folded to fit your pocket. Just like we have

portable memory, we can expect personal computers to take the form of portable dockets, which can be connected to any monitor for full desktop experience.

IoT devices are becoming a part of the mainstream electronics culture and people are adopting smart devices into their lives faster than ever. The Internet of Things will transform every aspect of our lives over the next decades and beyond. It will evolve to bring ultimate connectivity and transform every device to be able to interact with each other leading to Internet of Everything, as we may call it. By 2050, there will be 24 billion interconnected devices, meaning almost every object around us will be connected to the cloud and to the internet. Further, advancement of IoT will be influenced by the switch to 5G network. It will boost IoT capabilities by making mobile communication and data use faster and efficient.

The line between physical and virtual space will forever be blurred. With online gaming industry growing multifold, the next big evolution in the space is going to come from the most revolutionary technologies of our time – Artificial Intelligence and Virtual Reality. While Virtual reality immerse gamers into simulated environments so they actually feel like they're in the game, AI would make background characters, non-player characters (NPCs), in a video game more intelligent. These characters would be able to react to real-life players. From backlit 3D game consoles to PCs with the ability to run heavy-graphic augmented reality games, technology will become more mainstream and would take gaming to a whole new level by making it more engaging and exciting. The world-famous Pokémon Go was the first game to break augmented reality into the mainstream and we may see an even larger rise in the popularity of AR and MR (Mixed Reality) games in the near future.

The increasing ability of machines to learn and act intelligently will absolutely transform our world. Online gaming will become more mainstream, bridging the age gap and stirring active participation just like movies. VR has already changed the shape of entertainment drastically. Further, the future of entertainment is gaming. And the future of gaming is community. In the upcoming years we can expect new trends such as cloud gaming, online casino, more use of digital currencies and most importantly, enhanced and life-like in-game experience to evolve. This will create a huge demand for robust gaming equipment and PCs, encouraging OEMs to revamp their existing line-up and strengthen their gaming portfolio. Gaming world is already at its peak and the industry is getting bigger and better with time, with the future holding a lot of surprises for the community.

It's difficult to predict with any certainty what the future exactly holds, but when you consider how different things were just 20 years ago, it makes one realize that things will be vastly different in 2041 from what they are today. The last two decades exemplified the true potential of the PC industry, through remarkable inventions in terms of dual-screen devices, convertible laptops, detachable memory, and bezel-less display, giving us a glimpse of what the next 2 decades hold for us. We are entering an era of intensified innovation in PC industry. Computers are touted to become even thinner and lighter, faster and powerful, with elements that will enrich PC experience. We can see PCs going beyond 2-in-1 forms and come with detachable design or foldable/ flexible displays or keyboard-less interface or all of the above. The industry, driven by innovation and continued deployment of tools like AI, VR, IoT and 5G, will no doubt be a significantly different world in the next 20 years. I see a very promising future for the industry and curious to see it unfold in next 20 years.
