CEO and Co Founder, Yulu

India is deemed to be the fastest growing economy of the world. With rapid industrialization and mass scale urbanisation, we face the dichotomy of being a member of the Paris agreement with a commitment towards environment conservation. While India is also witnessing a growing consciousness towards sustainable consumption there lie a number of demographic challenges ahead. The growth of the new middle class with its unique demands needs a substantial supply to be created.

According to the modern-age mobility framework there are 5 fundamentals to mobility.

1. **Smart:** Convenient real time availability with instant planning and execution.
2. **Sustainable:** Green solutions with positive impact to the environment which is economically justifiable.
3. **Small:** Practical small sized solutions with a minimalistic design to reduce traffic congestion in small towns to big cities.
4. **Shared:** Lesser Vehicles on the roads preventing traffic congestion with one vehicle used repeatedly by different riders on use basis.
5. **Safe:** Solo ridership with natural social distancing especially needed during the Pandemic.

There is a need to redefine new forms of mobility with the boundless innovation that India has at its disposal. These features should be

Springing Ahead

the key drivers in the journey of the country to evolve its industry with modified features keeping in mind the following factors::

1. City Planning

India is remodelling its cities with a smart set-up to incorporate the demands of the future such as green spaces, paths ways and cycle lanes. There has been a viable accommodation of people from all walks of life making the Indian city planning a more equitable and inclusive one.

In light of these developments, a new version of mobility has to be matured which is both equitable and inclusive while being sustainable. These modes of Mobility must work on the principle of the 3 As - Accessibility, Affordability and Availability.

The 15 Minute Vision talks about the possibility of reaching from a given point A to point B in 15 mins by creating an ecosystem where people can live, work and play. And thus, the spaces that were allocated to cars running and parking are now being cut and appropriated to be used by sustainable alternatives like bicycles tracks and pavements for walking. The equation of public transport will be completed with shared mobility coming into the picture as the means to connect the first and last mile needs of the riders.

2. Ridership Dynamism

The number of females with a driving license is greatly outnumbered by males in India. Two wheelers are designed around males, and women have to risk their safety while riding them. As we focus on becoming more inclusive and gender neutral with equal opportunities in all walks of life, we need to manufacture without gender biases.

In modern India with the nuclear family type picking up pace, the elderly too need to be self resilient for their independent living. India will have a

demography with an inverted pyramid like structure where the 60+ will account for the dominant population. Thus, we need to envision a safe vehicle suitable for their solo commuting, starting now. Given the situation, India should have a compelling policy for EVs to deal with these dilemmas as it offers a lightweight engine and body with noise reduction and easy handiwork as a solution.

3. Technology

Technology enables digitalisation, efficiency and predictability, and guarantees transparency and access to its users. Electric vehicles and battery technology are likely to evolve with time and resources. In today's age of big data analytics, machine, and deep learning, technology is playing a pivotal role in many industries. The modern IoT Technology is driving force in creating UMaaS (Urban Mobility as a Service) which is an affordable and scalable solution of the first and last mile commute option to citizens

The Cross Cut

While our cities are choked, India still has one of the lowest penetration of personal ownership of vehicles, so the transition to shared and environment-friendly is expected to be faster. We have to visualize a canvas which is structured to the tune of building and creating livable cities of tomorrow. The Indian government is also nudging towards electrification of vehicles by proposing various schemes and incentives that make EVs a resourceful alternative to the gasoline or diesel vehicle. India can become a country where all mobility forms, public, private and shared, coexist and interact to create an enjoyable experience for all.

The citizens are enjoying the little joys of life and have realised the requisite for a minimalist lifestyle for the good of all. Because it's not about having more but making room for what truly matters.
