

What's in the fine print?

They talked a lot about the new Windows, here's what was there in the fine print.

Satvik Pandey | feedback@digit.in

There were a host of announcements during Microsoft's presentation where they showcased this latest in their Windows line of operating systems, Windows 11. As we told you earlier, naturally, there were some things that were lost in translation and you have almost all of them covered here in this article.

WINDOWS UPDATES

There was a major issue with Microsoft's update patterns and the impact that they had on the performance of the computers. With the release of Windows 11, the company announced that heading forward, there will be a reduction in the size of the Windows updates, making the

download and installation process easier when compared with that of Windows 10.

There's going to be a reduction in the frequency of the 'major Windows updates' too. Going forward, Microsoft announced that there would be only a single major update for Windows every year. Previously, with Windows 10, the company pushed itself to the limits in the bid to provide two updates a year, and we all know how it turned out for the users.

INNOVATION IS WELCOME!

More and more laptop and handheld device manufacturers have been shifting their focus towards building

Intel made the Lakefield CPUs with thin-and-light devices in mind

devices that not only provide great performance packaged in small form factors, but also great battery life. And, it seems Microsoft has opened Windows up to more innovations in CPU technology to flow in from manufacturers like Intel.

Windows 11 will ship with enhanced support for Hybrid Architecture CPUs – the ones with a mix of both power saving and high-performance CPU cores. We have already seen how successful M1 Macs have been with a similar implementation. How good future laptops will be at competing with Apple's M1 chips and their successors, only time will tell, but Microsoft certainly seems geared to tackle that from an OS perspective. While there were no explicit announcement, it feels like Microsoft has enabled Intel to battle Apple using its Lakefield line of CPUs. AMD too will no doubt be working on something similar as well.

XBOX-ISH

As was expected, a lot of the announcement event was focussed

Windows 10 had a notorious history of having unstable updates
