

Tag Heuer Super Mario Connected watch

Tag Heuer has introduced a limited edition of its Connected watch, created in collaboration with Nintendo. Naturally, we've got Super Mario himself getting comfortable on the watch's dial, encouraging and rewarding users when they achieve their activity goals. This is a digital watch from the Swiss watchmaker, and the idea came from wanting to

incorporate a gaming element into the Connected watch. The rest of the watch also features a design palette similar to Nintendo's mascot, with the red accents and themed UI. Iconic symbols from the game appear on the bezel, even the straps come in black on red, with Mario's M engraved on the strap buckles and the watch's crown. Mario shows up on the dial as users work towards their activity goals, such as step counts, and as the activity level goes up, Mario himself gets more amped with newer, and more livelier animations. Mario will unlock new animations at 25 percent, 50 percent, 75 percent and 100 percent of your daily target. The limited edition Tag Heuer Connected watch has only 2000 pieces, and will retail at \$2,100 each.

Samsung DDR5 RAM Stick

The arrival of Intel Alder Lake later this year should see the introduction of DDR5 RAM into PC builds. While the RAM requirements for the most part should remain the same, it hasn't stopped Samsung from working on some mammoth RAM sticks. Earlier this year it was reported that they were working on a 512GB DDR5 stick, but the capacity can apparently go even higher. As reported by Tom's Hardware, the company has announced that it's developing a new 24GB module that'll be able to fit up to 768GB onto a single stick!

We don't need to tell you that this capacity is overkill for even the godliest of PC builds, and we're afraid to even guess what it might cost. However, the 24GB option does look like something most of us can possibly look forward to. The typical gaming PC today has around 16GB of RAM, which is 16 times what it was two decades ago. If we consider that, RAM hitting the triple digits in the future doesn't seem implausible. Samsung hasn't announced a release window for their new DDR5 chips, so it's unlikely they'll be coming out this year.

The Sound Screw

There are many options when it comes to soundproofing a room, some people have insulation blown into the walls, others use thicker sheets of drywall, then you have additional sound proofing options like sound-absorbing panels which you can cover the walls with. This is often employed by recording studios, but the results aren't exactly easy on the eyes; it's not something you would want in your home. The Sound Screw developed by Håkan Wernersson of the Department of Materials Science and Applied Mathematics at Sweden's Malmö University is a sound damping solution that isn't unsightly, or comparatively heavy on the wallet. While drywall screws normally screw panels directly against the backbone or structure of the room, the Sound Screw features a spring below

the head. It still holds the drywall securely, but there's a slight gap between where the Sound Screw's spring can expand and compress. This basically allows it to dampen the energy of sound waves coming at the walls. During test runs, researchers found that Sound Screws were able to reduce sound transmissions by up to nine decibels.
