Record your own combinations

It must have surely happened that while working on your computer, you would have had a certain key combination attached to two different functions in two different apps. And, when you would have hit the key combination, a function that you did not intend to trigger at the time must have been activated. To avoid this very problem, Rectangle allows the users to configure their own key combinations to perform different functions of the app, that is, snapping the window to a particular position.

For adding your own key combination for actions, go to the menu bar, hit the Rectangle app icon, and navigate to the preferences menu. When in there, in the top bar of the preferences window, click the button that looks like the command key on your Mac keyboard. There you will see that certain functions have their key combinations already set. To change a pre-existing key combination, click the 'x' next to the combination

button, and when the button reads, Record Shortcut click it, and it will prompt you to key in your combination. Once you put that in, you will see that the key combination has been assigned to the action and will also appear in the drop-down menu of the Rectangle app.

Drag n snap 'em windows to position

You may be a long time Rectangle user, but the drag and snap function may have eluded your sight because many users rely on the shortcuts or menu options to reposition their windows. But the drag and snap function allows the users to use the cursor to drag the windows to the desired position so that they snap into position.

To use this, you will need to exit the full screen mode of the window you want to allot a position to. Then, take the cursor to the top border of the application, and make sure that you can move the window. After this, all you need to do is drag the window to one of the many different positions on the screen to

snap them in place. For example, if you want your window to occupy the right half of the screen, you will have to drag your window to the right edge of the screen and let the mouse button go when the shader, showing the position of the snapped window appears. Likewise, for every different window position, there are points where you can drag your window to to make the magic happen. Hop on and explore the capabilities of the app.

Mind the gap

Rectangle also provides its users with the option to change the gap that is there between the windows when they are spread out on the screen. By default, this value is set to 0, meaning all your windows would be placed side by side, right next to each other. To change this, you will

A shader showing the position to which the window would snap to

again need to go to the Preferences page. Here, instead of clicking the command button like option, you will need to click on the button labelled as the gear icon. There, you will find an option labelled as Gaps between windows, with a slider right next to it. From here, all you need to do is move the slider around until you hit the sweet spot in terms of the gap between the windows on your screen.

Hookshot

This is a companion app to Rectangle that makes snapping the windows to the screens even faster. The shortcuts and gestures can be used to snap apps out of focus as well. [\[1\]](#)
