You can pick your own formats and arrange them to your liking

anyone who needs to enter the exact numeric value of colour must have had a time where can use Colour Picker to instantly get numeric values of the colour that you are looking at.

The Colour Picker has three modes in total. The default, the colour picker with the editor mode enabled, the second one, the editor only mode, and the third, the colour picker only. Each of these three has their own purpose and use case, and you can explore them and configure your PowerTool prompt to start the colour picker in the mode you like the most. One setting that we would want you to look at when you are on the settings page of the colour picker is the one where you can change the order and number of colour formats that you want to use and the code to be displayed in. This setting can be found on the lower part

of the colour picker settings menu and is simple to use. Press on the arrows that appear next to the colour format to move it up and down the list and turn the colour formats displayed on and off by clicking the toggle to enable or disable them. For example, you need to work with four formats, like HEX, RGB, CMYK and NCol. You can turn off the rest of the colour format and change the hierarchy of the remaining colour formats to display the ones you like in the order you prefer to see them.

While users were only promised a better alternative to registry editors with PowerToys, what Microsoft actually gave us was a suite of tools for powerusers that expand the functionality of the OS, and a number of different ways to tweak the OS. There are plenty of options to tweak PowerTools itself.
