Teardown: Huawei Watch 3

Average upgrade when it comes to repairability

Dhriti Datta | dhriti@digit.in

Lack of replaceable parts

Most of the components on the sensor array are held in place by Philips screws or brackets, and a couple of rivets. However, the components are stuck on non-removable flex cables spelling doom for repairs. The sensor array itself is stuck to the back cover of the watch. In the end, there's only one replaceable element on the back cover – the loudspeaker. Repairability aside, the watch comes with a temperature sensor which isn't very common in smartwatches.

Behold the battery

Another small bracket must be removed out of the way to reveal the battery of the smartwatch. The battery is held in place with adhesive and requires careful disassembly. The power brick is rated at 1.78Wh (460 mAh @ 3.87 V) and the company claims it can offer 3 days of battery life. The Xiaomi Mi Watch (2021) packs a 1.62Wh battery while the Galaxy Watch3 comes with a 1.3Wh battery. Meanwhile, the Apple Watch Series 6 comes packing a much smaller 1.17Wh battery.

Harrowing opening procedure

The Huawei Watch 3's model name is GLL-AL04 and it sports a digital crown and a side button. There are four Torx screws securing the back cover that can be removed to start the opening process. However, the body is held together by some stubborn adhesive that needs heat and some slicing to come open. Additionally, the flex cable is also close to the back cover's edge, making it even more difficult to open successfully.
