Cleaning up audio

with Adobe Audition CC

Master audio tracks like a pro

Vaidyanathan S | feedback@digit.in

N

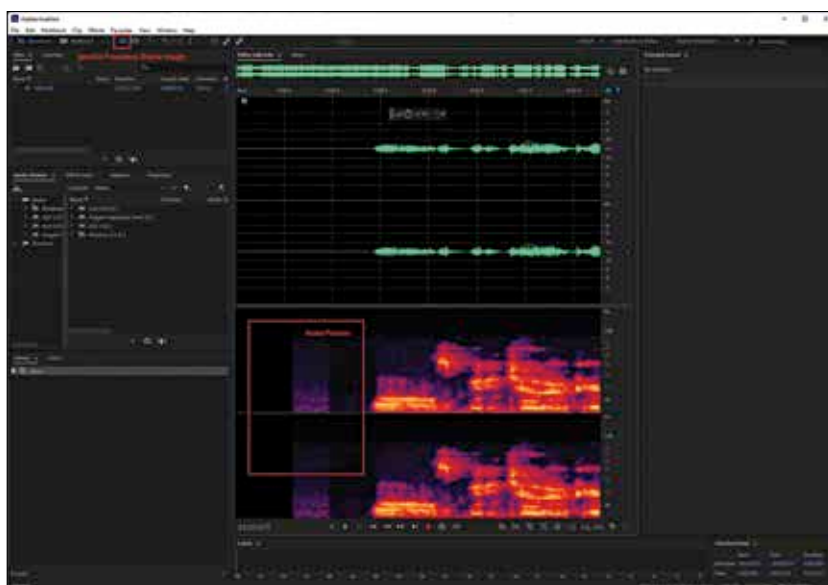

ot everyone has the luxury of owning studio-grade equipment but let that not dampen

your spirits. With Adobe Audition, it is very much possible to get your audio sound like a near-professional master.

PAY HEED TO DPC LATENCY

First things first. Before we get down to the nitty gritty of cleaning up audio using Adobe Audition, it is important to minimize latency issues, if any. In Windows, this is called DPC (Deferred Procedure Call) Latency, which is a fancy term to indicate how Windows prioritizes various driver requests. If your audio driver gets pushed back in the queue, you will hear random clicks, pops, and all sorts of annoying noises.

While latency issues can affect Macs as well, the problem is not very severe on macOS since there is a tight integration between the OS and the underlying hardware in Apple computers. Given the diverse device support in Windows, not all drivers are written equal adhering to Microsoft's best practices, so there's every possibility that an errant driver can jostle for prioritization over your audio hardware. Thankfully, there are a few steps you can take to fix this, and a way to check the DPC latency.

Identifying background noise pattern in the Spectral Frequency Display

Run a quick DPC latency check

It helps to identify where the problem lies before we move on to the troubleshooting. For that, run a quick DPC latency check using a free tool called LatencyMon.

1. Start up the utility and press the Play button on top. Let the tool analyze your system for a few minutes. Then, while the tool is still running, start doing various tasks on your PC.
2. We would recommend opening a few browser tabs, playing a short 4K YouTube video, and do stuff that are likely to result in a good stress on the CPU, GPU, or both.
3. Observe the LatencyMon window for any changes. Stop the test after a short while and note the "Current measured interrupt to process latency" and "Highest measured interrupt to process latency" values. The program will

let you know if it thinks that the latency value is too high for real-time audio.

4. You would then want to check the Drivers tab to see which driver is taking up the highest execution time. Usual culprits here include networking, GPU, and bad audio drivers. The workarounds include using a dedicated PC or at least user account, disable networking, ensure all drivers are up to date, and using the maximum performance mode offered.

REMOVE BACKGROUND NOISE

Unless you are in a professional studio, ambient noise is a common problem during most recordings. Audition makes it very easy to quickly (and effectively) remove most background noise patterns.

1. Fire up Adobe Audition CC and open your audio file.
