

Australia on 60% clean energy

Records smashed as renewables break through 60% output, coal output at a new low.

your preference. About a -1 to -5 dB Gain and a Tolerance between 10% and 20% should be a good starting point.

- After selecting the appropriate Gain and Tolerance levels, just hit Scan. Audition will now analyze the track and show the number of problems detected in the bottom of the pane.

- Now, just press Repair All and Audition will work its magic to normalize the waveform based on the set parameters. After the process is completed, you should see that all detected clipping artefacts have been remedied.

- If you find the DeClipper effect not satisfactory, you can always undo the action by pressing Ctrl + Z (Command + Z on Mac) and repeating the process with new Gain and Tolerance values.

Pro Tip: Sometimes, certain portions of the track may need to sound loud compared to the others. To do so, just select the desired part of the track and manually adjust the dB slider overlay to the desired value.

BOOST OR CUT FREQUENCIES WITH PARAMETRIC EQUALIZER

Parametric equalizer (EQ) is graphic EQ on steroids. It allows total control over the frequency range allowing you to say, simultaneously remove a certain frequency while boosting another. The frequency selection can be very precise, so you have full control over which range to remove and which ones to boost.

- Navigate to Filter and EQ in the Effects menu and then click on Parametric Equalizer.
- This opens a dialog that displays a graph and shows various selectable frequencies in the low, mid, and high ranges.
- Depending on the kind of track you are working on, you may want to

select the appropriate Band. For instance, if you are fine tuning vocals, you can deselect all except say band 5. Press Play or the spacebar to see the audio playing the EQ window.

Adjusting the EQ over a specific part of the sound

- On the desired band, adjust the Gain and Q / Width values as needed. If you are looking to remove random clicks or whistling sounds, adjust the Gain value to about 12 dB for starters and the Q / Width to about 20. This should result in a nice, tight curve.
- Play the clip by pressing spacebar and move this curve along the length of the clip. Notice where you observe clicks, whistles, or unwanted noises. In our example, we have positioned the curve over an area where there seems to be a breathing sound.

- Now that we have positioned the curve over a desired frequency that needs to be minimized, in the Gain field, append a negative sign for the value. So, if you have entered 12 initially, enter -12 now. This will invert the curve. Play back the file to see if the desired effect has been achieved and hit Apply to make the changes
- You can repeat the process for other frequencies and bands as well. You can make certain frequencies pop and reduce the

others by simple selecting the desired Band and altering the Gain values accordingly. Note that the resulting cleanup may not always seem prominent, but subtle changes also go a long way in enhancing the listening experience for your audience.

EXTRACT VOCALS OR INSTRUMENTS

Many a time, you would want to isolate and extract vocals or specific noises from the mix say for an Acapella effect, for instance. Audition has a nifty tool that allows you to do just the same.

- Under the Effects menu, navigate to the Stereo Imagery submenu, and click on "Center Channel Extractor..."
- Let's start with the Acapella preset for now (under the Presets dropdown). You can also select any other preset and work your way around or even create a custom one as well.
- Now, select a region of the clip that you think best represents the vocal range that needs to be isolated. *Note: This largely depends on the actual mix itself. Ideally, vocals that are mapped specifically to the Center channel result in the best possible isolation.*

Crossover Bleed and Phase Discrimination adjustment

- You can now play with the Phase Angle and Pan sliders to minimize the instrumentation and enhance the vocals. This also applies if you want to isolate instrumentation instead of the vocals as well.
