

FB to hide harmful content

Facebook said that Facebook will drive teens away from harmful content on its platform. <https://dgit.in/nov21-5>

The Notepad gets a redesign!

In the latest Windows 11 update, Notepad got a fresh look with rounded corners and condensed menus. <https://dgit.in/nov21-6>

Becoming a Computational Linguist

Help machines translate human languages

Dhruv Narula |
feedback@dgit.in

Computational linguistics is typically lumped in with artificial intelligence, yet it existed before artificial intelligence was developed. In the 1950s, efforts in the United States to use computers to mechanically translate writings from foreign languages, particularly Russian scientific journals, into English gave rise to the domain of computational linguistics. Historical attempts to recreate older versions of modern languages and sub-grouping modern languages into language families have also used computational and quantitative methodologies.

When machine translation (also known as mechanical translation) failed to produce appropriate translations very immediately, it was realised that automated processing of human languages was significantly more sophisticated than previously thought. The term of the new branch of research dedicated to developing algorithms and software for intelligently processing language data was coined as computational linguistics.

It was discovered that in order to translate one language into another, one must grasp both languages' grammar, including morphology (the grammar of word formations) and syntax (the grammar of sentence structure). To comprehend syntax, one must first comprehend semantics, lexicon (or 'vocabulary,') and even some pragmatics of language use. As a result, what began as a project to translate across languages has grown into a field dedicated to learning how to represent and interpret natural languages using computers.

QUALIFICATION

With up and coming fields of study, the more expertise and experience you have, the better your prospects will be. Employers usually expect a Master's Degree but most of them will be fine with a Bachelor's Degree. As for experience, anywhere from 1-3 years of experience

would be required to get yourself a job in a well-known firm. Candidates are expected to be detail-oriented, be familiar with programming languages such as Rust and Python which are commonly used with Natural Language Processing (NLP) applications. Any other scripting language on top of that is always welcome.

Bachelor's Degree

Prospective linguists should look for bachelor's degree programmes in computational linguistics, linguistics, or computer science to prepare for an advanced degree. A linguistics bachelor's degree programme may include general linguistics as well as a speciality. Language acquisition, phonetics, computational linguistics, and syntax may all be included in linguistics bachelor's degree programmes. Learning a foreign language as a graduate student may aid aspiring computational linguists intellectually and professionally. Students pursuing further degrees in computational linguistics or linguistics are frequently required to speak a foreign language. Fluency in a foreign language is also required by some jobs in the field of computational linguistics.

Master's Degree

Graduates with a master's degree in computational linguistics are often qualified for jobs in industry or research. A master's degree in computational linguistics can also help students prepare for doctorate work in the discipline. Specific programme requirements vary, but graduates are typically expected to be conversant with coding languages and natural language processing.

If someone wants to teach or conduct research at a university, they should consider getting a doctorate. Students interested in pursuing doctorate studies might pick between a degree programme in computational
