Problems with third-party display replacement

The flood illuminator and the dot projector for Face ID have been merged into a single module that allows for a narrower notch this year. The problem that occurs is that any kind of display replacement makes Face ID stop working entirely. It looks like the display is serial-locked to the phone, so third party repairs for displays will lead to users losing all Face ID functionality. A massive blow to your right to repair.

Pro

Hard to access earpiece speaker and front-camera

The earpiece speaker has been replaced this year and it sits between the front-facing camera and Face ID hardware. One of the speaker's standoff screws is under the logic board, so you'll have to remove the entire board to swap the speaker. Not so repair friendly... The front-facing camera hardware is underneath the earpiece speaker, again under the logic board, so it isn't easy to access this as well.

Layered logic board

The layered logic board in the iPhone 13 Pro is even tinier this year. These are the chips on the board - Apple APL1W07 A15 Bionic SoC layered with 6 GB of SK Hynix LPDDR4X SDRAM, Apple/USI U1 ultra-wideband chip, Apple APL1098 power management IC, and others. On the lower layer, you find 128 GB of Kioxia NAND flash memory, Qualcomm SDX60M 5G modem, USI 339S00761 WiFi/Bluetooth module, and a few more chips.
