TECHNOBABBLE 2022

Gartner has released the strategic technology trends for the next year, so let us have a look at the world salad that is going to be served in the boardrooms of evil megacorporations.

DATA FABRIC

All the large successful organisations are driven by data, but they are struggling to use all the data that they collect. Research has shown that 74 percent of the data collected in most organisations is not used and 82 percent is locked up in silos. Data fabric is a management architecture for data that allows for organisations to rapidly use data across the organisation, in a way to centrally govern the data no matter where it is, in the cloud, edge and IoT devices, as well as local servers. A Forrester report commissioned by IBM showed that enterprises could boost their ROI to anywhere from 86 to 158 percent, with the implementation of a data fabric architecture.

CLOUD NATIVE PLATFORMS

The best example of a cloud native platform is Netflix, where the entire infrastructure for the application runs in the cloud. When

Netflix made the move in 2009 to be entirely on the cloud, the approach had not been proven, but Netflix managed to use Amazon Web Services to its advantage. Netflix pioneered the switch from a monolithic software architecture to one that is broken up into microservices, where each service is developed independently from the others. So for example the user signup process, discovery or search service was moved from Netflix servers to the cloud, and developed independently of the others. More companies are looking to move entirely to the cloud, and the Netflix Open Source Software Center has a whole bunch of tools for anyone to implement microservices of their own.

DISTRIBUTED ENTERPRISE

Distributed organisations such as banks, retailers, hospitals and government agencies tend to build extremely secure digital walls around the headquarters, but leave off all the branches with less

secure perimeters. Cybercriminals tend to compromise the branches, then use that as a base to compromise the headquarters. The hacks on Target and Home Depot were conducted in this manner. In a distributed enterprise, the security for the entire organisation is considered as a unit, which involves central management of the cybersecurity of the entire organisation, as well as centralised application control and prioritisation. Basically it means that people with boring jobs will have their Facebooks throttled.

COMPOSABLE APPLICATIONS

The distributed enterprises of the future will need to use composable applications, which are a combination of cloud native platforms and data fabric. A combination of in-house and purchased microservices are used in a composable environment, where it is easy to mix, match and swap components. The advantage of composable applications is that the business logic
