can be embedded within the APIs between the microservices, allowing for rapid changes across the various ways in which consumers interface with the businesses (known as touch-points), and preventing data from being trapped in silos. Amazon for example is perfectly positioned to use composable applications to provide novel services to its users, by mixing and matching its existing services in unique ways.

CYBERSECURITY MESH

The distributed enterprise cannot use the traditional approach of building a large security perimeter around the headquarters and smaller fences around the branches. At the same time, it has to protect a hybrid multicloud environment, the composable cloud native applications, and all the data. The idea is to have a horizontal, distributed approach for cybersecurity, instead of a monolithic top down approach. It means building small security perimeters around each access point. A centralised authority has control over each of the nodes, and even if any one of the nodes gets compromised, the rest of the organisation is still protected by the mesh. The guiding principle here is to go for a modular, and therefore flexible approach to secure the network.

DECISION INTELLIGENCE

This is an emergent discipline where social sciences, managerial science and data science all come together. Decision engineering is a related field of improving the decision making process, but does not include the data science aspect of it as well. The idea is to essentially use game theory as well as data science to mitigate, work around or avoid rare but disruptive "Black Swan" events. The approach has been used to make batteries in vehicles more efficient, to deliver more targeted marketing to customers, and to accurately forecast inventory requirements in the manufacturing sector.

HYPERAUTOMATION

The pandemic kicked the world into a phase of hyper-automation, where it became necessary for organisations of all shapes and sizes to quickly move an increasing number of their processes into the cloud. This is a threshold beyond which automation allows for an increase in the amount of automation, which causes a hyperautomation. A part of hyperautomation is using AI to automate undocumented processes with unstructured data points and processes that previously could not be automated. Robotic process automation allows for creating armies of

This cat does not exist. Sorry.

tireless virtual workers that can intelligently discover processes on their own, and provide valuable insights from every part of the process, which could be cumbersome or impossible to gather from humans.

PRIVACY ENHANCING COMPUTING

One of the widely known examples of privacy enhancing computing that we have seen recently are the contact tracing apps, that have all the components required for a privacy enhancing computation system. There is an environment for processing data in a secure way, a decentralised approach for gleaning insights from the data, and the data as well as the algorithms being encrypted before any analytics or processing is done. The future

data cows (that's us humans) are concerned over how large evil multinational corporations use their data (according to Pew Research Center research, it's 79 percent of adults), and the PEC approach may go a long way in reassuring people that their private and sensitive data is safe.

AI ENGINEERING

The question of how and where to apply AI technologies to solve problems, is what the emerging discipline of AI engineering hopes to answer. AI engineering is a guideline for what kinds of problems are best solved by AI, how to collect, maintain and use vast troves of data, ensuring all decisions can be accounted for and justified, continuous monitoring of the system for security and embedding ethical considerations into all parts of the system. The three pillars of AI engineering is that the AI is human centric, scalable and secure. Carnegie Mellon University is spearheading the National AI engineering initiative in the USA. Researchers from Microsoft and Google are involved with the initiative.

GENERATIVE AI

In the September issue of the magazine, Boo Man used a service called rytr.me, and until very recently, these tools for generative articles were not very good. At best, an intelligent editor could re-order and rewrite the generated content to fix the text. There are now tools that can realistically generate rigged human characters as well as terrain and foliage, which are sold as middleware for games. The website thisxdoesnotexist showcases the power of generative AI by producing images of everything from horses, startups, foodstuff, houses and people at the click of a button. Generative AI is just getting started, and we can expect to see a lot more content generated by AI, especially when it comes to videos and marketers will be leading the charge. **d**
