internet. Hence, it can function fully even if you never connect to an ISP.

BLOCKCHAIN GAMES

A blockchain game is one in which the assets utilised in the game are decentralised in terms of ownership and storage, i.e. the in-game assets are owned and operated by the players. NFTs are a vital component of blockchain gaming because of their capacity to confirm ownership and validity and their ability to be readily exchanged between parties.

1. Axie Infinity

Axie Infinity is an NFT based Pokemon style game. Players breed and gather Axies with the primary objective of battling other gamers (NFT-based digital creatures). You will earn a Smooth Love Potion (SLP) as a reward for each mission, adventure mode, or player-versus-player (PVP) fighting. On the Ethereum blockchain, it is a play-to-earn game.

2. Sandbox

Sandbox is a well-known NFT game platform for generating and trading various virtual goods. It is an open-world physical sandbox. Sandbox allows players to modify and commercialise voxel creations in a similar way to Minecraft. For building and altering objects, the platform includes several tools. Another significant element of NFT games is that you may sell the goods on numerous markets. Sandbox 3D introduces SAND, an ERC-20 cryptocurrency, as the metaverse's native currency. When playing Sandbox 3D, you may spend this token to purchase in-game items.

3. Decentraland

Decentraland is a user-owned virtual environment where users may create,

explore, play games, socialise, and profit from their efforts. MANA is a fungible ERC20 cryptocurrency token created by Decentraland. MANA is used for trading commodities and services given by its users, as well as LAND parcels. Decentraland is divided into a small number of pieces, each represented by LAND, a non-fungible digital asset held in an Ethereum smart contract. As the owner, you have complete creative control over your work, and any profits you create go right to your wallet. The ATLAS tool may also be used to browse Decentraland's topography and themed districts to discover the optimal development spot.

DeFi

DeFi, short for Decentralized Finance, is a financial ecosystem that does not rely on a central point of authority, unlike traditional economic systems like banks and government regulated entities. Some of the most prominent DeFi applications/ecosystems are:

1. AAVE

AAVE is a decentralised lending network for crypto assets that allows users to lend, borrow, and earn interest. There is no need for a mediator when utilising AAVE because Ethereum smart contracts power the system. AAVE runs a loan pool to address the issue of mediators. All of the money that individuals desire to lend is collected and put into a pool. Individuals can also borrow from this pool. You must have a collateral asset to borrow from the liquidity pool, which means you must possess Cryptocurrency and deposit it as a security for the amount you wish to borrow. Depending on the token that the user wants to borrow, different levels of collateralisation exist due to volatility in the value of coins.

2. Uniswap

Uniswap is a decentralised financial system that uses smart contract technology to allow you to buy, sell, and exchange coins on the Ethereum blockchain. Uniswap is decentralised, so users retain complete control

over their cash. People may become liquidity partners, which means they can pool their money with other people on the Uniswap platform, allowing transactions. Uniswap pools everyone's liquidity and uses a deterministic algorithm to create markets. An automated market maker (AMM) algorithm offers prices to the end-user based on a set of predefined rules. As a liquidity provider, you will get a portion of every trade that uses the liquidity pool in which you have placed your assets.

3. UMA

UMA is an open-source financial contracts platform that aims to make it possible for anybody to construct collateral-backed synthetic assets without requiring permission or trust. It allows users to link their tokens to the price of anything via contracts known as Derivatives. It aims for a future in which assets may be built and manufactured to track the price of anything, including physical assets like gold or global equities like Tesla or Amazon. Its mission is to provide anyone with an internet connection to have equal access to the derivatives market.

4. Maker DAO

MakerDAO is a digital vault where users may deposit various Ethereum-based cryptocurrencies and use them to mint DAI, the Maker ecosystem's native stable coin. Rather than relying on trust, the loan is secured by the value of the assets you deposit, which in Maker's instance is Ethereum. Maker's true genius is that it leverages the opening, closure, and liquidation of these collateralised Debt Positions as a mechanism to keep the DAI stable coin at or around its \$1 value, guaranteeing that its value remains constant without any centralised intervention.
