Make your own AR filters using SparkAR

Every social media app has its own filters and they offer a unique way for creators to express themselves. Here's how you can make some using SparkAR

A

R (Augmented Reality) has been around for almost four decades now and it's popularity and use cases have always left users awestruck. One of the most common uses of AR is in camera filters especially ones that let users enjoy and be entertained by creative implementations of these AR filters. Spark AR Studio is one such application which empowers users to create AR effects for Facebook and Instagram easily. Let's have an indepth look at Spark AR Studio and see how we can make our very own basic filter.

SPARK AR STUDIO

Before jumping into our tutorial, let's go through the basics of Spark AR Studio. First we take a look at the Scene panel of Spark AR Studio:

This panel is what you will be greeted with when opening your project(s) and here you will add the objects and animations that will make up your effect.

As you would notice, there are also objects that are already present here:

1. An ambient light and a directional light. These are responsible for giving your 3D effects realistic lighting. So, in case you are working with 2D objects, you can remove them.
2. The Device and Camera represent the device that the effect is playing on, and the camera reproduces it's view. These are some essentials that cannot be removed.
3. The Microphone is used to capture sound detected by the device's microphone, which might be useful depending on the type of effect.

Next up, the Layers panel is located next to the Scene panel and allows you to create and customise the layers in your effect. Scene objects are placed in front of or behind each other using these layers only.

ADDING OBJECTS TO YOUR EFFECT

An effect is primarily made up of multiple objects in your scene which the user might interact with. To add an object available in Spark AR Studio to your project, you can do either of these:

1. In the Menu bar, click the Add button.
OR
2. At the bottom of the 'Scene panel,' click the Add Object button.

Objects in an effect serve different uses like, the plane tracker will detect a real world surface, for instance a floor. The face tracker will detect the movement and alignment conditions of someone's face.

You'll also notice the video in the interface's centre. This very area is known as the Viewport, and it's where you can keep track of your effect while it's being worked on. Suggestion: blank video allows you to build effects in the back camera better.

The camera feed is something which is quite important for your effects as well, and you can change the video if you want too. In order to do that:
