Teardown: Nothing Ear (1)

Discovering something
in "Nothing"

Dhriti Datta | dhriti@digit.in

Peeking inside the earbuds

The earbuds are partly-transparent and partly-opaque, allowing the users to get a glimpse at some of the innards without having to open them up. The opaque part can be opened with a bit of heat and some careful prying with a spudger. Unlike the clean look of the transparent part of the buds, the opaque part has some adhesive action going on inside.

Disconnecting the in-ear portion from the stem

In order to disconnect the top angled in-ear tip from the stem, you need to carefully remove the red-coloured adhesive that glues a press-fit connector to its socket. There's no heat required for this step and you can simply use tweezers to pry away the adhesive and disconnect the flex cable.

Definitely not nothing

There's certainly a lot more than nothing inside the Nothing Ear (1)s. The in-ear portion of the earbud features the driver and the battery. There's also a microphone on the flex cable that is positioned precisely in order to provide effective Active Noise Cancellation. The earbud houses an 11.6mm driver and a voice coil with a diameter of 5.7mm. There's a driver grille that can be pushed aside with the help of a spudger as well.
