

Remove crypto-based games

South Korea has asked Apple and Google to remove crypto-based games from app stores. <https://digit.in/jan22-71>

NFTs to fund campaign

Korean presidential candidate Lee Jae-Myung issued NFTs to those who donated to his campaign. <https://digit.in/jan22-72>

134 minutes. It also pushed optical composting techniques to perhaps their greatest achievements yet during the film's space battle sequences.

After you've read everything mentioned above, it will probably be very understandable to you as to why the progress of

FACTOID

Out of the 10 million dollar budget for ET, 1 million was spent on the creation of ET himself!

technology and digital techniques was slow in the 1980s. They were still very experimental, time consuming and quite expensive.

Here's a short list of a few notable contributions made to the field of VFX by various movies:

- 2010 (1984) introduced computational fluid dynamics to the VFX toolkit
- Flight of the Navigator (1986) introduced reflection mapping to create the silvered skin of the alien craft
- Labyrinth (1986) featured the first CG creature (an owl)
- Willow (1988) offered the first really convincing morphing sequences
- The Abyss (1989) showed that CG water was possible

- Total Recall (1990) used motion capture for the first time to create its 'moving x-ray' sequence.

PUTTING CG ON THE MAP!

The 90s started off with a bang and showed the world how good digital graphics had gotten. The movies that showed it off were James Cameron's Terminator 2: Judgement Day and Steven Spielberg's Jurassic Park.

Make no mistake, there was tons and tons of traditional work done in Terminator 2 as well such as exquisitely filmed models being used in the opening fight sequence and the crashing truck in the end, air cannons blew models of Los Angeles and quite undoubtedly, there was tons and tons of makeup. But it was ILM (Industrial Light and Magic), George Lucas' SFX company which he had made specially for Star Wars, whose work on the T10000 that really stood out. Being the first proper CG character after the glass knight in Sherlock Holmes and used reflection mapping and new morphing techniques that could convincingly map 2D images onto 3D animated objects to produce sequences such as the robot rising out of a checkered floor.

It was indeed very impressive for the audiences but just 2 years later, with the combined efforts of Steven Spielberg, ILM and Softimage 3D, out came Jurassic Park which used incredibly complex animatronics for much of it's dinosaurs but in reality, it was the CG dinosaurs that truly stole the show.

Just eleven years after TRON, the promise of CG had largely already been fulfilled. This was partly down to the stately progress of Moore's Law, partly down to the skill of a growing army of computer-based individuals, but it was also very much a period of transition in the VFX industry. Now it was time to see what the new breed of virtual VFX technicians could do.

CONCLUSION

Today, we can finally see how far we've come.

In the latest marvel movies behind the scenes, we don't see a single picture without a green screen or

FACTOID

It was originally decided that the go-motion technique which involves moving the animatronics ever so slightly in every frame and then using motion blur to make it a moving piece would be used but after seeing a T-Rex walk demo made using Softimage 3D, the production decided to go with CG for 50 of the dinosaur shots

Mark Ruffalo in a motion capture suit, or any other actor for that matter.

From Blue Screens to Green, From miniatures to motion capture and CG, we've truly come a long way.

And that is appropriately enough where we finish the history and origins of VFX in cinema, with the knowledge that just because it can be done, doesn't always mean that it should be. There are tons of things involved in making VFX a reality such as cameras, tricks, lenses and software – that the industry has developed over the years and is crucial in making the movies of today that we all love to watch so much. **d**
