SOLAR SYSTEM'S GAS BUBBLE

It's why we have twinkling stars

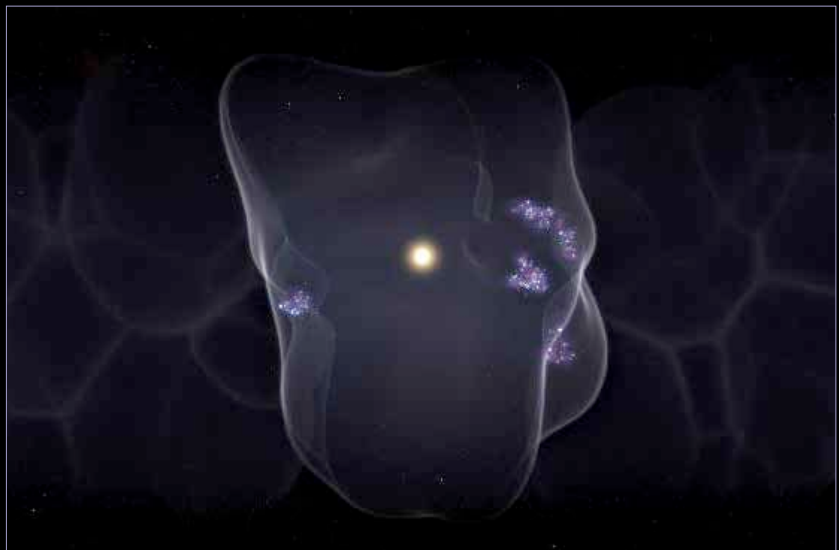

Satvik Pandey | feedback@digit.in

A

nyone who is remotely interested in space would know how mysterious and

exciting the happenings of our solar system are. There are a lot of questions that are still unanswered despite the hundreds of satellites and exploratory devices that we have sent out to investigate. One such question was about the Local Bubble, which has been known to house our solar system. Now, it has also been confirmed to be the place where the stars that we see in the night sky are formed.

In a paper titled, 'Star formation near the Sun is driven by the expansion of the Local Bubble' authored by a team of astronomers, the evolutionary history of the Local Bubble was explored, and major findings were reported which uncovered a lot of secrets. While drafting what is being called a 'true origin story', the researchers used data made available from the Gaia space observatory of the European Space Agency to explore the depths of the Local Bubble, which has been the resting place of our solar system for millions of years now, and also the site of star formations that we often

see in the night sky. The data sets used in the research were a part of the ESA's Gaia Early third Data Release (EDR3), which was released in December last year.

As revealed in the research paper, the history of the special neighbourhood that we are in right now started about 14million years ago, when a number of supernovas started exploding in space. These explosions released

hot gases, which combined to form the very first stage of the Local Bubble. As time passed, the explosions kept on taking place, and the Local Bubble kept on expanding. On the surface of this expanding bubble were clouds of interstellar gas and dust. These clouds then collapsed over time to form the stars that we see today in our skies. There were thousands of such clouds, which contracted to form stars all around.

This spacecraft is a blessing

A BUBBLY AFFAIR

How does it matter to us? When it all started to take place, the sun was far away from the Local Bubble. But as the bubble grew and the solar system as a whole, with the sun at its centre, started moving, about 5 million years ago, it entered the Local Bubble and became a part of it. Now that the solar system was in the bubble, the star formations of the 1000
