and rebuilt it into the Iron Monger, as he could not replicate Tony Stark's arc reactor technology. To tackle Iron Monger, Stark used the Mark III armor powered by the original Mark I Palladium core Arc Reactor, which unfortunately was not powerful enough. He therefore made Pepper Potts overload the large arc reactor powering Stark Industries which overloaded Stane's suit, electrocuting and rendering the latter unconscious. Following this, Stane fell into the large reactor which resulted in the destruction of the Iron Monger Suit, as well as the Mark II Arc Reactor, and killing Stane.

Palladium Arc Reactor Mark III:

The Mark III Palladium Arc Reactor was used by Tony Stark for powering his armor between the events of Iron Man 1 and 2, and was created to replace the one stolen and eventually destroyed by Obadiah Stane. However, Stark soon began to notice the Palladium Core's adverse effects on his health, gradually poisoning him, and eventually replaced it with a new element. Furthermore, this was also the first the first Stark experimented using an integrated reactor in the Mark II armor, which was however, later stolen by James Rhodes to create what came to be known as War Machine.

New Element Arc Reactor Mark I:

The New Element Arc Reactor was created by Tony Stark when he discovered the molecular structure of and synthesised a new element hidden in a diorama of the 1974 Stark Expo, using a hand built particle accelerator and the assistance of his AI computer, J.A.R.V.I.S. The new element thus synthesised by Tony Stark was not just infinitely more powerful, of which an enlarged example was its use to power Stark Tower in later movies, but also reversed the poisoning caused by the Palladium core arc reactors in Stark's body. It first powered the Mark VI Iron Man armor.

New Element Arc Reactor Mark II:

The Mark I Arc Reactor was

replaced by the Mark II to power the Iron Legion group of armors built during the events of Iron Man 3. It comprised armors between the Mark VIII and Mark XLI. The Iron Legion however, was destroyed after Stark instructed Jarvis to self destruct the suits. Furthermore, towards the end of Iron Man 3, Stark himself had the electromagnet and all the shrapnel in his body removed surgically, ending his own dependence on arc reactors for his survival. He therefore threw the Mark II Arc Reactor into the sea with what is perhaps one of his most memorable dialogues: "You can take away my house, all my tricks and toys. One thing you can't take away, I am, Iron Man."

New Element Arc Reactor

New Element Arc Reactor Mark III:

The new arc reactor was used to power Iron Man's Mark XLIII armor as well as the Mark XLIV extension, better known as the Hulkbuster, used by attaching it to the base armor that is the former. It was created as a safeguard against the Hulk's uncontrollable rage and subsequent rampage, and was used to do so during the events of Avengers: Age of Ultron, to contain the Hulk in South Africa. The Mark XLV armor also used this Arc Reactor along with a new, hexagonal Chest Repulsor Transmitter design giving it more efficient power distribution which in turn allowed for faster flight, quicker repulsor blast charge times, as well as higher intensity of said blasts.

New Element Arc Reactor Mark IV:

The Mark IV New Element Arc Reactor was used by the Mark XLVI and the Mark XLVII suits. It borrowed from the design of the Mark XLIV's multiple repulsor transmitter design, allowing for an armor to operate even with the main reactor being damaged. It also allowed for faster repulsor blasts, both in flight and on the ground. The main repulsor transmitter's unibeam, powered by this reactor, was powerful enough to destroy the Winter Soldier's bionic arm in one go.

New Element Arc Reactor Mark V:

The second most advanced arc reactor designed by Tony Stark, the heart shaped New Element Mark

Reactor was the first to be capable of storing the nanoparticles required to assemble and power Iron Man's latest Mark L nanotechnology armor, along with all its extra attachments. The nanotech suit along with its attachments particularly the Energy Displacer Cannons, powered by this reactor was easily able to overpower Cull Obsidian in New York.

New Element Arc

Reactor Mark VI: The most advanced and final arc

reactor designed by Tony Stark, the New Element Arc Reactor Mark VI combined the features of the Mark V and Mark III New Element Arc Reactors, while retaining the visual design of the former, albeit slightly larger in size. This was the only reactor which could be supercharged without it being damaged in the process. It housed the nanoparticles of the Mark LXXXV and all its modules, the final Iron Man armor. It was powerful enough to vanquish Outriders, Thanos' and the Black Order's soldiers in one single blast. Smaller variants of this reactor were also made, powering the Mark XLIX armor, and the Iron Patriot Mark II armor, without the nanoparticle storage technology however.
