

Google Chrome

Google Chrome's logo was changed for the first time in eight years, but the change is subtle. <https://dgit.in/mar22-45>

Lawsuit against Google

Google sued for \$2.4 billion after being charged with breaching European Union antitrust laws. <https://dgit.in/mar22-46>

interact with the real world. The data is fetched from the real world using Chainlink, a decentralised modular oracle network that allows you to bring data into your smart contracts. Every smart contract requires a currency wallet (the most common being ethereum). And the best wallet used by almost every blockchain developer is called MetaMask.

METAMASK

To interact with ethereum, we will need a wallet. One of the most common wallets is Metamask, which supports Chrome, Edge, Brave etc. browsers. On downloading Metamask, it will act as an extension on the top-right corner of your screen, so you can view your ethereum currency whenever you want by clicking on the extension.

After adding Metamask as an extension, you need to create a new wallet. You can do that by clicking on the "Create a Wallet" option. You are putting real money in your wallet, right? So it needs to be secure and backed up. Metamask contains a secret phrase backup setting, where you will be given a secret phrase (also known as "seed phrase") to keep and memorise. This phrase should not be revealed to anyone, as the person who knows this has unlimited access to your ether and all the accounts you create under this wallet.

After getting the "secret phrase", Metamask will ask you to verify your secret phrase. Once matched, your account is ready! Mind you, this secret mnemonic phrase contains the access

to all your MetaMask accounts. So protect it with a password manager. Additionally, MetaMask gives you a new account with a unique address that is visible to all. You can create more than one account in MetaMask, and each account is differentiated with its unique address and private key. Guard your private key zealously.

MAINNET VS TESTNET

While working with real money, people usually write smart contracts on the ethereum mainnet. However, developers wanting to test their app are not keen on spending real money in the testing phase. Hence, they use a backup network called "Rinkeby Test Network", which resembles real-world ethereum transactions on the web. You can switch to this network by toggling with buttons on the top-right of your MetaMask interface.

YOUR FIRST WEB TRANSACTION

Using this Rinkeby Test Network, you can actually do your own first transaction! There is a website called "Faucet" which gives people free tokens, which is like free Rinkeby ethereum for testing purposes. To acquire these funds, you'll have to make a simple tweet where you add your visible account address.

After tweeting, you need to copy the link to your tweet and paste it into a website called <https://faucet.rinkeby.io/>

[rinkeby.io/](https://faucet.rinkeby.io/) which distributes this test ether. You can select the amount you want, and the number of days from the toggle button given. After you click on "Give me ether", you can go and check your account on the Rinkeby Test Network and you will notice that you have received the amount you requested. Viola, this is your first transaction!

Since this is a real-world test transaction performed on the web, you can view its details on any block viewer. For the Rinkeby Test Network, you have to use <https://rinkeby.etherscan.io/> (an alternative to etherscan.io, which is the traditional block viewer for real ethereum transactions).

This is a small sneak-peek into the world of blockchain development. There are many other technologies involved to apply blockchain on the web. If this got you intrigued about real-world blockchain development, there are many resources online to help. For now, we hope this helped you get started with understanding blockchain, smart contracts, writing in solidity and witnessing a transaction as you deploy your smart contract. [🔗](#)
