

Pocket-sized Doom

Nowadays, when you think Doom, you think fancy high-end PC with ray-tracing capabilities etc. You don't think small enough to fit in your pocket. But that's exactly what Adafruit has done.

They ported the Retro-Go firmware for ESP32 devices, which is basically used to emulate a range of old consoles like the NES, Game Boy, Atari Lynx and more, onto a tiny QT Py ESP32 Pico board. That's it, you could run Doom on it, and it even had full mod support, thanks to the WAD architecture the game uses. The tiny handheld also has six tactile buttons, and sound too, so you can listen to the classic Doom soundtrack in all its glory. The tiny 1.3-inch 240x240 screen works well with the old graphics, making it look pretty crisp overall. All in all, this is probably one of the smallest Doom-capable consoles we've ever seen. If you do manage to get your hands on one, just be careful not to leave it in your pockets and put it in the washing machine.

27,000,000mAh power bank

YouTuber Handy Geng was apparently not too happy about the fact that all his friends had bigger power banks than he did, so he went ahead and possibly created the world's largest portable powerbank, with a capacity of a whopping 27,000,000mAh. You'd need at least 900 regular sized power banks to match that. The massive power bank comes outfitted with 60 sockets, and it can charge 5,000 phones with 3000mAh batteries before it runs out of juice. Of course, it can also charge laptops, electric bikes, other power banks, electrical appliances and more. Measuring around 180cmx120cmx30cm, this massive power bank is also technically portable, as long as you've got the accompanying rope to pull it around.

According to Hendy, thanks to his enormous powerbank, he doesn't have to worry about power outages anymore, sure it's a hassle to drag the thing around, but you're pretty much carrying a personal power station around. If you're interested in building your own absolute unit of a power bank, you can go check out YouTuber Handy Geng's channel, where he's got the making-of this power bank.

BOE 500 Hz monitor

According to a report from Chinese outlet Sina, BOE has built the world's first 500 Hz gaming monitor. The 27-inch Full HD panel is equipped with a high-mobility oxide backplane which is what allowed BOE to achieve the high refresh rate, all with a response time of 1ms.

If you've been following gaming monitors, then you'll notice that 500 Hz is significantly faster than the fastest gaming monitors in the market today, which top out at around 360 Hz. Of course, 360 Hz is also incredibly fast, which makes achieving 500 Hz all the more impressive.

However, BOE's monitor design is still in its prototype stage and was designed for demonstration purposes only. There has been no word from the company on whether they'll actually be producing these for the market or not. So, that's up in the air.

Then again, even if you actually could get your hands on a 500 Hz monitor, there's still the question of practicality. You would need an accompanying GPU capable of pushing 500 frames from a game, which let's be honest, is not happening anytime soon.

And we mean both getting a GPU, or GPUs hitting 500 FPS. Still, it's nice to dream to have.
