

GOING FOR THE PERFORMANCE CROWN!

Big and bigger performance

Soham Raninga | feedback@digit.in

We caught up with Marcus Kennedy from Intel, talking about the all-new 12th gen processors from Intel and the big performance gains that it brings to the table. From the all-new hybrid architecture, to how it stacks up against the competition, we've got a whole lot of insight on how Intel sees the 12th gen processors make a big impact on the desktop as well as the laptop market.

d The 12th gen is a big big change in terms of the approach towards mobile as well as desktop processors and

also as the platform as a whole, with the big-little sort of architecture that it brings in, can you help us understand the thought process behind this approach?

I actually like to call it big and bigger and not big little. There are two kinds of cores in this architecture, the P cores which are the performance cores, and then there are the E cores which are the efficiency cores. The P cores are the highest performing cores that we've ever made. They are designed to deliver enthusiast-level performance, while the E cores are the efficiency cores, based on a different architecture, they are not small cores when it comes to performance either.

In fact, they compare very favorably to our previous skylake generation in terms of performance. So, its a combination of our previous generation and packing it with our newest generation cores. And, that's why I like to call it big and bigger because the performance level when you put these together is very, very high.

You talked about the shift being a significant one for us and

yes, the new performance

hybrid architecture is a big shift in our X86 architecture in more than a decade, bringing the core micro-architecture cores into a single product.

The P cores are the highest performing cores, built for maximum burst and for highest single-threaded per-
