

ments, we all know how important they are in an application or a website. The fonts used and the sizing of the text in an application or a website can literally define how user friendly and successful it is. Sometimes, certain fonts and the way that they are used can also become a part of the product's identity. So, when developing in Adobe XD, it is important to know how to use the Text tool, which is the next in the line during the basic development process.

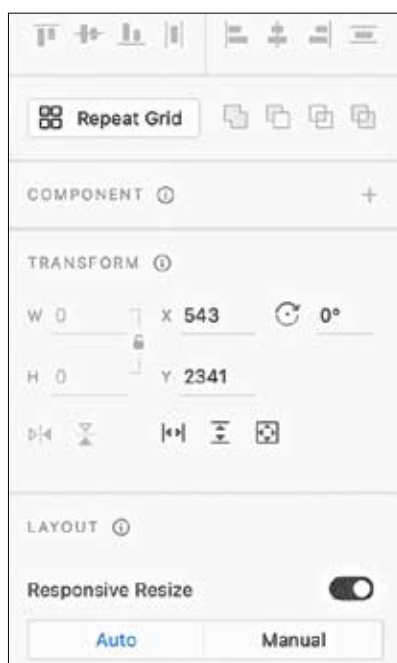

To add text to the artboard, you need to use the text tool, which is represented on the left side toolbar of the application using the letter T. Click on it, and it will be activated. Then you can mouse over to the area that you want to and click once to start adding text. Once you are done, the text block will be converted into an object which can be transformed and edited like the other objects on the artboard. To change the font of the text that you are adding, you will need to navigate to the Property Inspector, where you will see the options to change the font, resize the text and change other related properties listed under the Text category.

Tweak your fonts to perfection

COMPOSING THE COMPONENTS

During the process of app and website development, there are certain design elements like action buttons and toggle switches. In Adobe XD, these are added using the Components option. In the Property Inspector, it is presented with the same name in its top section. To convert an element on the artboard into a component, select the object and click on the + icon in the Component category in the Property Inspector. Alternatively, you can also right-click on the selected object and click on the

The Component section in the Property Inspector

Make Component option in the drop-down menu. All the created components appear in the Assets panel.

When creating copies of components, you need to note that each component listed in the Assets panel in XD is a main component. This means that any changes made to one instance of this component will result in changes being made and reflected in the others, irrespective of their placement within the project. But, if you make changes to a repeated instance of a component, it is marked as an instance with overrides and will preserve the changes that are made to that particular instance. The basic types of overrides are Text, Bitmap, Size, Appearance, and Layout.

Components also allow for dynamic changes to occur to their state when interacted with. To define a new state of a component, select the component and in the Property Inspector, where the component is listed, right-click and choose a state to define by clicking on the + button next to the default state text. Once you have done that, select the new state that has appeared and make changes to the component.

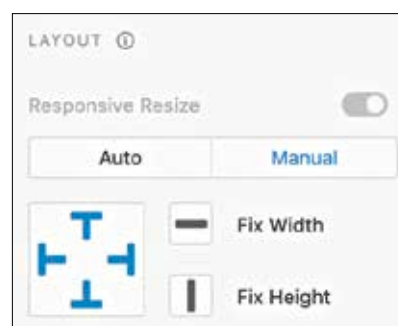

If you want to add interactivity to the component, you can do that too. The first step is to switch to Prototype mode. Click on the component you

want to add interactivity to, and then select the action that triggers that interaction using the options from the menu listed under the Interaction option on the Property Inspector. Now, pick the state as the destination of the component, and you are set.

LAYING IT ALL OUT

In the last few sections of this article, we have already covered Layouts in parts, so there is no point repeating all of it again. But the thing that we did not cover in the earlier paragraphs is the feature of XD that allows you to manually edit the resizing constraints while you are working with different components on an artboard.

To manually change the values of the constraints, all you have to do is select the component or object on the artboard that you want to change the responsiveness of, and then head over to the Property Inspector and locate the Layout section listed under which is the Responsive Resize toggle. Turn that on and switch the

The alterable constraints in the Layout section

mode from Auto to Manual, and the options to change the individual constraints will appear in front of you. Choose whatever settings you want to, and you will be set.

LINKING IT ALL UP

Once you have all the elements and components designed to the level that would put the best artists to shame, now is the time to change them from a simple collection of elements into a collection of interdependent elements, whose functionality would be nested to give birth to the application or website that you set out to make. The first step in the process is to switch the mode from Design to Prototype.
