will be needed before the tech can be produced for the general public.

FUTURE OF WIRELESS CHARGING TECH

The ability to charge devices with batteries or even power devices without the use of power and charging cables is obviously fantastic. Yes, with our current level of technology wireless charging is quite inefficient and results in a lot of wasted energy. To prove that for yourself, you can measure the units of electricity used to fully charge a device (for example a smartphone) with the use of a cable and then measure the same using the current wireless charging tech. You'll notice that the same amount of charge has taken significantly more units of electricity if charged wirelessly over the wired counterpart.

manufacturing in a production line, it has not yet been adopted for other processes. The reason is primarily to do with power. The robots in a production line do not move around much and the production line needs to be modified to adjust for that lack of motion. Now, imagine a factory floor with a dozen or so robots that can move around freely without the need for cables that power them and make it a dangerous work environment. If this wireless charging technology can be scaled up, it can be used in commercial applications like this to power (or at least extend the battery life) of wireless robots. Strategically-placed emitters can ensure a huge area is within the purview of the wireless charging field and many other appliances can be powered using the same. This can also have an impact on safety. Jobs that are hazardous for hu-

PRIVATE APPLICATIONS

Homes and Societies – If the technology ever gets to a point where it is efficient enough, compact enough and cheap enough to be adopted by the general public for private uses, we can hope to see it in our homes and offices. Rooms that are most frequently used can have a wireless charging device installed in them to allow your personal portable devices with wireless charging capabilities to be charged when in the operating field. Similarly, corporate offices and buildings can install larger devices with the same concept.

Roadways and parking – The ultimate evolution of this kind of technology would probably be wireless chargers installed in the roads. Imagine this. Roadways full of electric vehicles that are constantly charged while driving thanks to wireless charging emitters

The findings were published in the IEEE Transactions on Industrial Electronics Journal.

Over time, of course, these technologies will improve and become more efficient, to a point where wireless charging and wireless power would be efficient enough for it to actually be considered for the other benefits they provide. So let's explore some of the examples where wireless charging can be used in the future in both, commercial as well as private scenarios.

COMMERCIAL APPLICATIONS

Robotics – The manufacturing sector has been adopting robotics for quite a while. Now, most of our mass-produced goods have had some kind of robotic influence in their manufacturing process. However, while robotics are prevalent when it comes to

mans such as mining can be taken over by these wirelessly-powered robots with minimal setup. This sector could benefit greatly from wireless charging technologies such as this.

Restaurants, Pubs and Coffee Shops – As this technology would be considered novel in the initial stages, it could be used by eateries to attract crowds to their establishments. A bit like Wi-Fi back in the day and the robotic arm that serves coffee in San Francisco. Since the wireless charging devices have a limited range, tables closer to the device can charge a premium compared to the tables away from the device similar to how tickets are sold for sporting and live events.

installed in the roads themselves. That would mean extended battery range thanks to constant charging or even the total elimination of range anxiety. Powerful wireless chargers could also be installed in areas such as parking lots and garages to make electric vehicle charging simple and easy.

It's not difficult to see all the benefits that wireless charging and wireless power transfer bring to the table. The technology is still a few years or decades away in terms of it being adopted by the general public. We also need to worry about all the safety issues that can crop up while using this technology. But if some of the teething problems can be ironed out, it's very likely that our future may be truly wire-free. **d**
