Coachella in Fortnite

The annual music festival announced it's deal with Epic Games to launch Coachella-themed skins and features. <https://digit.in/may22-71>

TURN OFF ANIMATIONS OR SPEED THEM UP

When you switch between Android apps and screens, you spend some of that time looking at animations and waiting for them to fade away.

By altering the Window animation scale, Transition animation scale, and Animator duration scale parameters in Developer options, you can completely eliminate these animations. You can also speed up animations, if you like them but wish they were faster.

This can make moving between apps almost instantaneous on a fast phone or tablet. If you thought your Android phone was quick before, try turning off the animations and

watch how much faster it becomes.

SPOOF GPS LOCATION

Allowing mock places lets you set fake GPS coordinates to fool Android into thinking you're somewhere you're not. You may use this option with a software like Fake GPS location to fool your Android device and the apps running on it into believing you're somewhere you're not.

What purpose would this serve? You might, for example, spoof a GPS check-in at a location without really

visiting it, or fool your pals in a location-tracking software by teleporting around the planet.

ENABLE MSAA FOR OPENGL GAMES

If you have a high-end phone or tablet with excellent graphics performance and play 3D games on it, there is a way to improve the appearance of those games. Simply enable the Force 4x MSAA option on the Developer Options box.

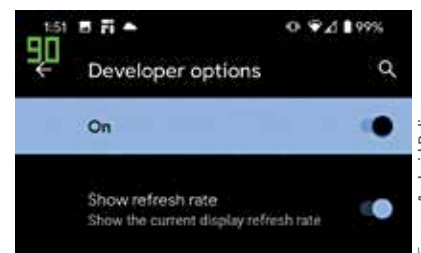

This will force OpenGL ES 2.0 games and other apps on Android to use 4x multisample anti-aliasing. This necessitates greater graphics processing power, which will deplete your battery faster, but it will increase image quality in select games.

OVERLAY REFRESH RATE

Modern-day smartphones come with multiple refresh rate

options ranging from the conventional 60 Hz all the way up to 144 Hz. Some smartphones even come with LTPO panels that allow the display refresh rate to adapt according to the content on the screen. This allows for battery preservation since the display can bring the refresh rate all the way down to 1 Hz when the situation calls for it, hence improving power efficiency. If you've ever wondered what rate your screen is refreshing at in a particular app or window, you can find out via Developer Options.

Developer Options allows users to activate refresh rate overlay on their screen that lets them monitor the current refresh rate, which is especially useful for panels that have adaptive refresh rate. Keep in mind that this toggle does not show frame rates. To enable this, head to Developer Options > Show Refresh Rate. Turn on the toggle

and a Fraps-like overlay will appear on the top left corner show the screen's current refresh rate.

So, get tweaking away with these helpful Developer Options tips and tricks. There are multiple more tricks possible via Developer Options. Let us know if you'd like a Part 2 of this article by writing in to editor@digit.in. **d**
