

ISRO to launch GSAT-24

GSAT-24 satellite built by ISRO will be launched on Europe's Ariana-V Rocket from Kourou on June 22. <https://digit.in/jun22-64>

Out of body experience

For the first time ever, human liver preserved outside the body for 3 days used for transplant. <https://digit.in/jun22-65>

today claim to excel at every step, in reality, none of them are perfect. All four phones, including the Xiaomi 12 Pro, fail to effectively handle the extra heat that's created by the powerful chipset at hand. To test this, we did a quick surface temperature check after stress testing the phones for 30 minutes.

Of the four, we found the OnePlus 10 Pro overheating the most, as it went up to 44.6 degrees. The Xiaomi 12 Pro also ran hot, with the phone going up to 43.7 degrees. The S22 Ultra, with its big cooling chamber managed to remain relatively cool, with the phone only touching the 42.8-degree mark. The Realme GT 2 Pro also ran hot but did manage to do a better job than the other phones as it only touched a surface temperature of 42.3 degrees.

Even though the thermals for all four phones are definitely not alarming, there is no denying the temperatures of these phones could go up to uncomfortable levels if the stress test was conducted in a setting with higher ambient temperature than the one in our test labs. But even at these levels, they are slightly higher than the highs recorded on Android flagships from last year. This metric for phones such as the S21 Ultra and the OnePlus 9 Pro was below the 40-degree mark, which is still high, but not as high as the ones we're seeing on the current generation Snapdragon flagship chipset phones.

DO THE HIGH TEMPS AFFECT PERFORMANCE?

Now to the all-important question: does the high temperature on these Snapdragon 8 Gen 1 phones affect real-world performance? Well, for this we pushed the three phones to the limit by running a number of benchmarks and also tested their real-world performance by playing a few games on them.

Benchmarks and a few CPU-GPU intensive games are the only places where you'd see the chipset showing any signs of stress. For basic tasks such as browsing the internet or using apps like Twitter, Instagram, and their ilk, all three phones perform equally well. There's really nothing here to differen-

tiate them on the basis of performance and none of them misses a beat, making sure the user's interactions with the phones are smooth and lag-free.

Moving to benchmarks, we began our tests using AnTuTu where we got some interesting results. All four phones proved more than competent. However, when it came to performance, two phones from the list lagged severe-

ly behind, with the other two, clocking some seriously good numbers.

Surprisingly, it was the Galaxy S22 Ultra and the OnePlus 10 Pro which did not do too well in this particular benchmark. In fact, the scores of the OnePlus 10 Pro were even lower than some phones running the Snapdragon 888 SoC. Both the Realme GT 2 Pro and the Xiaomi 12 Pro absolutely hit it out
