tion or other sleep disorders that reduce sleep quality or duration can have adverse effects on the health of a person. Regular sleep deprivation can lead to various effects and health issues which can lead to heart failure, heart disease, heart attack, high blood pressure, strokes, diabetes and various other ailments. It is estimated that 90 per cent of people suffering from insomnia also have another health condition brought on because of the lack of sleep.

Depression – One of the most vicious effects of sleep deprivation comes in the form of depression.

And the reason why it is considered vicious is that sleep loss and depression tend to feed off each other making both worse. Sleep loss can result in intensifying the symptoms and effects of depression and depression, in turn, makes it more difficult to sleep.

Sleep loss can affect you like alcohol – Being awake for too long can result in the dulling of reaction times, impairs judgement, reduces concentration and also adversely affects memory. A large number of accidents on the roads and in industries that require the operation of heavy machinery occur due to the operators feeling drowsy due to lack of sleep. It also affects reasoning, learning and memory which can affect everyone.

Lowers Immunity – While sleeping, our body repairs and renews a lot of functions and cells. One of the things that the body creates while you sleep are the antibodies that are needed for your immune system. If a person is sleep-deprived, the body does not get the chance to build its immune system

and bring it back up to optimal levels. And with a compromised immune system your body loses or at least decreases its ability to defend against bacteria and viruses.

Weight gain – Sleep affects various hormones in the body. Two hormones that are responsible for the feeling of hunger and fullness are ghrelin and leptin respectively. When someone is sleep deprived, the brain reduces the amount of leptin and raises the amount of ghrelin in the body which makes the person feel more hungry. The increase in the feeling of hunger can increase the person's consump-

tion of food as well. Combine that with the lack of sleep making you feel too tired to exercise and you are left with a recipe for obesity.

Ageing skin – You would never think that something like the lack of sleep would affect your skin but it does, and it can affect people of all ages as well. You see, when the body experiences too little sleep, it releases excess quantities of the stress hormone called cortisol. And cortisol has the adverse effect of breaking down skin collagen. For kids, it's doubly worse because lack of sleep can reduce the amount of the human growth hormone in the body which is in charge of (apart from the growth of muscles and bones) thickening skin.

PREVENTION AND TREATMENT OF SLEEP DEPRIVATION

Prioritisation of rest and sleep – In the modern age, sleep is often overlooked as a priority and is ignored the most in the face of other objectives. The most common cause of sleep deprivation arises due to work and deadlines along with personal and

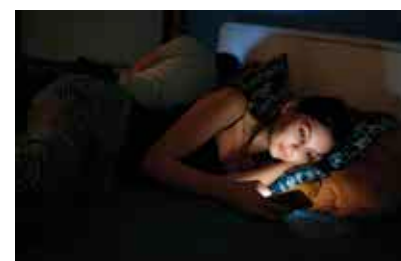

social commitments. Overall, it is important to set boundaries when it comes to work and social obligations and prioritise sleep.

Making it a routine – Most sleep-deprived people do not have a set routine when it comes to their sleep schedule. Sleeping and waking at odd inconsistent hours can affect the natural circadian rhythm which results in a lower quality of sleep. Making sleep a priority and a routine requires a conscious effort.

Reduce Naps – It may seem counterintuitive that the way to prevent sleep deprivation is by reducing naps. But naps during the day, especially in the later parts of the day can have an adverse effect on getting good quality sleep at night. If one must nap, it should ideally be before late afternoons and try to keep the naps below 30mins.

Reduction of Electronic use – Well, judging that you are reading this in Digit Magazine, we assume

this point won't sit well with you. But it is pretty much common knowledge at this point that the use of electronics like smartphones, PCs and tablets affects sleep because it keeps your mind stimulated and at the same time the light emitted by our modern electronic devices is very similar to daylight which messes with the circadian rhythm of our body.
