The end of HDDs?

Agent001 gets wind of some developments in the storage space

Agent001 | agent001@digit.in

A

analysts and tech reviewers have been ringing the death knell for HDDs ever since the first SSD hit

the market. Of course, they were ridiculed because SSDs cost 70-130x more than HDDs back when they were first introduced but that's no longer the case any more. The bullish growth that the smartphone market has enjoyed for the better part of the last decade meant that memory manufacturers have been extremely busy scaling up their facilities to meet the high demand. And the silicon shortage issue that was aggravated by the pandemic also saw silicon manufacturers scaling up their production facilities. The end result of all that has been a massive drop in manufacturing costs leading to much cheaper SSDs.

At the time of writing, a decent 1 TB NVMe SSD that can provide read and write speeds in excess of 1500 MBps can be purchased for around ₹8,000. And if you throw in an additional ₹1000 bucks, then you could potentially double the speeds of the SSD. I kid you not, check out the speeds of the Kingston NV1 and the WD SN570 and the prices for which they sell. Both great SSDs, and both are from different performance segments, yet they're closely priced. Simply

because of the ridiculous competition in the market. Even premium SSDs which hit the limits of x4 PCIe Lanes can be obtained for ₹13,000.

Compared to these SSDs, the humble hard drive continues to stagnate at the ₹3100-3400 mark. So for a little over double the cost, you can get more than 20x the performance. This seems like a no brainer since the performance uplift is tremendous and yet, the humble hard drive continues

decades. Compared to that, SSDs used to have a much lesser life time because of the wear and tear that they undergo due to regular usage. Current gen SSDs have figured out newer methods of mitigating concentrated wear and tear but there's the expectation that your SSD will conk off around 5-7 years.

The biggest decider of whether a certain medium of storage will retain a decent market share is the

to sell like hot cakes in countries such as India. A good chunk of these are going into DIY desktop PCs since hard drives offer a reliable means for storing data over long periods of time. If handled properly, hard drives have been known to last for multiple

consumer pre-built market. These include pre-built desktops and more importantly, laptops. Laptops, by far, make up for the largest market share of storage devices. Even data centres don't come anywhere close at the moment. And if certain companies
